NOTE

The first section of this volume, entitled "Bureau of Fisheries," constitutes what was known in years prior to 1933 as "Report of the Commissioner of Fisheries." Since then, in the interests of economy, it is a reprint from the "Annual Report of the Secretary of Commerce." The pagination, therefore, is the same as that of the Secretary's Report, rather than beginning with page I. This report covers two administrations of the Bureau of Fisheries. Commissioner Frank T. Bell resigned, effective March 21, 1939, and the duties of that office were assumed by Charles E. Jackson, as Acting Commissioner, on that date.

U. S. DEPARTMENT OF COMMERCE

BUREAU OF FISHERIES

HEADQUARTERS STAFF, 1938-39

Acting Commissioner Charles E. Jackson

0

Administrative Assistant.—John R. Gardner.
Chiefs of Divisions:
Fish Culture.—Glen C. Leach.
Inquiry Respecting Food Fishes.—Elmer Higgins.
Fishery Industries.—R. H. Fiedler.
Alaska Service.—Ward T. Bower.
Black Bass and Anglers.—Talbott Denmead.
Director of Aquarium.—Fred G. Orsinger.
Editor.—Harold B. Carr.
Librarian.—Gladys Johnson.
Publications.—Baebara Aller.

IV

BUREAU OF FISHERIES

Available statistics indicate that there was a decrease in the volume but an increase in the value of fishery products taken in the United States and Alaska during 1937 as compared with the preceding year. Data on the catch were collected for both 1936 and 1937 in the Chesapeake, South Atlantic and Gulf, Pacific, and Lake States and in Alaska. The combined catch in these sections alone shows a decrease of 13 percent in volume but an increase of 7 percent in value. Decreased catches were made in each of the five geographical sections; however, the principal reductions occurred in the Pacific Coast States where greatly reduced catches of pilchards were taken, and in Alaska where there was a large decline in the catch of salmon.

The total catch of fishery products in the United States and Alaska. as based on the most recent surveys, amounted to 4,352,549,000 pounds, valued at \$100,845,000. About 130,000 fishermen were

employed in making this catch.

210101-40---1

The production of canned fishery products in the United States and Alaska during 1937 amounted to 742,197,000 pounds, valued at \$105,175,000; the output of byproducts was valued at \$36,804,000: the production of frozen fishery products, excluding packaged products, amounted to 103,112,000 pounds, estimated to be valued at \$8,800,000; and fresh and frozen packaged fish and shellfish, 201,803,000 pounds, valued at \$27,678,000. Based on surveys for previous years, the production of cured fishery products amounted to 104,839,000 pounds, valued at \$15,635,000. It is estimated that about 686,000,000 pounds of fresh fishery products (excluding packaged fish and shellfish), valued at about \$57,000,000, was marketed during 1937. The total marketed value to domestic primary handlers of all fishery products in 1937 is estimated at \$251,000,000.

Fishery products imported for consumption were valued at \$50,636,000 and domestic exports were valued at \$14,567,000.

The value of the production of canned fishery products in all sections increased 11 percent as compared with 1936; byproducts increased 5 percent; frozen fish, about 1 percent; and packaged fish, 3 percent.

INTERNATIONAL RELATIONS

HALIBUT INVESTIGATIONS

The International Fisheries Commission continued the investigation and regulation of the Pacific halibut fishery, under authority of the treaty of Jauary 29, 1937, between the United States and Canada.

In fulfillment of its regulatory duties, the Commission recorded the catch from each regulatory area, forecast and announced the date

185

of attainment of each area limit, and closed the areas accordingly. It opened the 1939 fishing season on April 1 under regulations essentially unchanged from those of the preceding year.

Areas 1 and 2 were closed to halibut fishing in 1938 at midnight of July 29, with catches of approximately 706,000 and 22,923,000 pounds, respectively. Areas 3 and 4 were closed at midnight of October 29, with catches of 25,591,000 and 0 pounds, respectively.

The investigations of the Commission's scientific staff were continued along the lines necessary for fulfillment of the purpose of the treaty. Current biological and statistical data, which form a system of observation of the changes occurring in the stocks of halibut as a result of regulation and a necessary basis for the continued rational control of the fishery, were collected and analyzed. The collection of biological data made necessary the operation of a vessel at sea.

The abundance of halibut, as indicated by the catch per unit of fishing effort, showed a further increase all along the coast in 1938. In area 2, between Cape Spencer in Alaska and Willipa Bay in Washington, the abundance was 15 percent greater than in 1937, 100 percent greater than in 1930. In area 3, between Cape Spencer and the Aleutian Islands, it was 3.5 percent greater than the previous year and 77 percent greater than in 1930, the last year of unrestricted fishing.

Sampling of the stocks of marketable halibut by means of market measurements was continued to determine the changes occurring in their composition as a result of regulation. For the first time since the Commission began regulating the fishery, market measurements failed to show an increase in the size of the fish landed or in the proportion of mature fish on the more depleted banks of area 2. The maximum proportion of larger sizes from the stock of young available at the time regulation began appears to have been reached and a further increase in the larger sizes may not occur until the increasing stock of young has had time to grow up.

Observation of the effect of regulation on the production of spawn in area 2 was continued by means of net hauls taken at sea during the winter spawning season. Analysis of the catches of eggs indicated that the increase observed in their abundance from 1934-35 to 1936-37 was not continued in 1937-38 and 1938-39. No special significance can yet be attributed to the failure of production in the latter 2 years to equal the high level of 1936-37, because of the variations that occur normally from year to year among marine species, but it is to be suspected that it may be associated with the changes in size composition mentioned above.

INTERNATIONAL PACIFIC SALMON FISHERIES COMMISSION

Work of an experimental and preliminary nature, to establish facts upon which the permanent program could be based, was carried on during the 1938 season. A compilation and analysis of the great mass of existing records of the sockeye run to the Fraser River was nearing completion by the end of the year. A survey of the spawning grounds was begun. The adult migrants in salt water were tagged and extensive recoveries made on the spawning grounds.

The Commission held its third meeting September 28-24 in Vancouver, B. C. The program of investigation, then under way, was discussed and that for 1989 approved. In February 1939, William A. Found resigned and was replaced by A. J. Whitmore.

JAPANESE ACTIVITIES IN THE BRISTOL BAY FISHERY

Japanese fishery operations in Bristol Bay in 1939, the tenth consecutive season in which such activities have been carried on, were confined to the catching and canning of king or spider crabs, and only one floating cannery, together with auxiliary craft, was employed. This indicates a continued adherence on the part of the Japanese Government to the assurance given in the spring of 1938 that its official survey of the salmon in Bristol Bay would be suspended and that it would issue no license to vessels to take salmon in those waters.

CONSERVATION OF WHALES

The Protocol of June 24, 1938, which amends in certain particulars the International Agreement for the Regulation of Whaling, signed at London on June 8, 1937, came into force as to the United States on March 30, 1939, and was proclaimed by the President on April 8, 1939.

The principal provisions of the Protocol of 1938, which are advances in the measures of conservation of the whale stock of the

world provided in the agreement of 1937, are as follows:

(1) A prohibition against the taking or treating of humpback whales south of 40° south latitude by factory ships of whale catchers attached thereto from October 1, 1938, to September 30, 1939. (Article 1.)

(2) The establishment of a sanctuary for baleen whales south of 40° south latitude between 70° west longitude and 160° west longitude

for a period of 2 years from December 3, 1938. (Article 2.)

(8) A clarification of provisions in articles 7 and 8 of the agreement of 1937, which had given rise to conflicting interpretations, so as to make clear that no factory ship which has been used for the purpose of treating baleen whales south of 40° south latitude shall be used for that purpose elsewhere within 12 months from the end of the open season; that only factory ships which have operated within the territorial waters in 1937 shall so operate after the signature of the protocol; that such ships shall be treated as land stations, shall remain moored, and shall not operate more than 6 months in any 12-month period; and that such operations shall be continuous. (Article 3.)

NORTH AMERICAN COUNCIL ON FISHERY INVESTIGATIONS

The twenty-fifth meeting of the North American Council on Fishery Investigations was held in Boston, Mass., October 4-7, 1988. Representatives from Canada, Newfoundland, and the United States were present. At the invitation of the Council, members of the Fishery Advisory Committee of the Department of Commerce and other leaders of the fishing industry attended a general session on

October 5 for a discussion of fishery problems in the North Atlantic area. The general program of fishery investigations being conducted by Canada, Newfoundland, and the United States was presented.

In the sectional committee meetings dealing with groundfish investigations, shorefish studies, hydrographic research, and fishery statistics, nearly a score of investigators presented reports on their work, affording members of the Council a summary review of progress during the year in these fields and permitting them to modify their official program accordingly. Important advances were reported in the study of the cod fishery being prosecuted by Canada, the lobster studies in Newfoundland, and the investigations in the United States leading to a proposal for effective management of the haddock fishery.

INTERSTATE COOPERATION IN FISHERY MANAGEMENT

As a result of efforts of the Council of State Governments in cooperation with the Bureau of Fisheries and with fishery administrators of the various States concerned, progress has been made toward the solution of fishery problems in the Great Lakes and on the

Atlantic coast.

The Interstate Committee on Great Lakes Fisheries, appointed at the conference held under the auspices of the Council of State Governments in February 1938, met in Chicago on December 5. An international treaty to bring about uniform regulation of Great Lakes fisheries was again endorsed. Pending the adoption of an international treaty, however, the Committee recommended the adoption of an interstate compact for the regulation of United States fisheries in the Great Lakes. The formation of such a compact has been authorized by the Congress of the United States. The Committee also urged that State fish and game commissioners be given discretionary power to regulate fisheries without legislative action.

At the Eastern States Conservation Conference held in New York November 19, a resolution was unanimously adopted petitioning Congress to grant permission to States bordering on the Atlantic coast to enter into a compact for the protection of migratory fishes in territorial waters. A committee was appointed to prepare a draft of the

compact for submission to the States.

FISHERY ADVISORY COMMITTEE

The Fishery Advisory Committee met in Boston, Mass., on October 5, 1938, in conjunction with the National Fisheries Convention in session during the week. Discussion centered largely around problems of production and merchandizing fishery products. On October 5, members also attended a general session of the North American Council on Fishery Investigations for consideration of fishery problems in the North Atlantic area.

lems in the North Atlantic area.

The Committee met in Washington, D. C., January 30-31, 1939. Special problems challenging the industry at this time, recommended by the Committee for further research, are improvements in methods of transporting iced and frozen fishes and more complete utilization of the waste products of the fisheries. Inasmuch as fishery products constitute a wholesome and nutritious food which contains mineral

elements essential to health that are not readily available in many foods of land origin, an even flow of fishery products from producer to consumer is essential to the public interest.

DOMESTIC RELATIONS

COOPERATION WITH FEDERAL, STATE, AND OTHER AGENCIES

Cooperation was given by members of the Bureau technological staff to chemists and bacteriologists of the Food and Drug Administration, U. S. Department of Agriculture, in connection with the development and application of tests on methods of determining the quality and constituents of various fishery products; and to the Extension Service of the U. S. Department of Agriculture in connection with the conduct of demonstrations and practical instruction on the preservation of fishery products and more complete utilization in the diet of the excellent food value of fish and shellfish.

Members of the economic and marketing staff of the Division of Fishery Industries cooperated with the Department of Labor in holding conferences with fishermen's unions and associations to settle disputes. The Division also worked with various Federal agencies in obtaining statistical data on our fisheries. These included the Bureau of Agricultural Economics, the health authorities in Wash-

ington, D. C., and the Bureau of the Census.

The Bureau has carried on cooperative investigations in technological work with several colleges, universities, and other State institutions. Outstanding among these are Washington State College, Pullman, Wash.; University of Washington, Seattle, Wash.; University of Maryland and Maryland State Agricultural Experiment Station, College Park, Md.

In the conduct of its statistical and marketing work some form of cooperation is given the Bureau in virtually every State where commercial fishing is prosecuted. This cooperation probably reached its greatest development in the States bordering on the Great Lakes and

in the Pacific Coast and Chesapeake Bay States.

The Division of Fish Culture maintains the closest liaison with the State fish and game departments and other Federal agencies concerned with the conservation of fish. There has been close contact between the Bureau's representatives, the Bureau of Reclamation, and fisheries officials of the State of Washington with reference to the development of plans for the artificial propagation of the salmon run to be affected by the completion of the huge Grand Coulee Dam.

There has been continued expansion of the policy of routing fish applications to the State departments for check and approval before deliveries are made. The natural consequence of this has been a development of arrangements for the States to deliver the fish with their own equipment and this has been practiced in a number of

instances.

The exchange of eggs and fish by the Bureau has been of mutual benefit, particularly in Michigan and Minnesota. In the Western States also, particularly in Oregon, the fish-cultural and fish-distribution work is closely coordinated, with resultant economies to both the State and the Federal Governments.

In the Tennessee Valley area, three-way agreements between the Bureau of Fisheries, the Tennessee Valley Authority, and the States of Alabama, Tennessee, and North Carolina have been made effective or are being negotiated. Under such agreements the T. V. A. has established and built hatcheries and rearing facilities which the Bureau is to operate. The fish produced are to be distributed by the States in that part of the Tennessee Valley area which are included within the respective State boundaries.

The work with the National Park Service has continued in a constructive way and at the close of the year the Park Service was constructing a new hatchery at Glacier Park with subsequent operations

to be managed by the Bureau.

In view of the tremendous responsibility upon the Forest Service of the Department of Agriculture for the maintenance of fishing in the national forests, the Bureau has enjoyed unusual cooperation with that agency. A new trout-rearing unit was under construction in the Allegheny National Forest in Pennsylvania, under plans developed and approved by the Bureau with the expectation that it

would be operated by this Bureau upon completion.

The State of North Dakota Fish and Game Department donated the site for a new hatchery at Valley City. At St. Louis, Mo., the city officials have approved the construction, at no cost to the Bureau, of a modern hatchery and service building in the Forest Park hatchery. This series of ponds was taken over by the Bureau for operation shortly before the start of the fiscal year 1939 and the results have been most favorable. The State of Minnesota donated a tract of land for a hatchery at New London and furnished the services of surveyors and engineers in acquiring additional property. The site for a new hatchery, at Farlington, Kans., was more easily acquired by reason of the donation of water rights to a State-owned lake. The State of Ohio purchased and donated to the Bureau a splendid location for the new hatchery to be constructed in that State.

CONSTRUCTION ACTIVITIES

At the start of the fiscal year there was being undertaken an extensive program of hatchery development and improvement financed by an allocation of \$808,500 from the Public Works Administration, and

\$500,050 from the Works Progress Administration.

These funds were allocated to more than 70 different field projects, involving complete rehabilitation of some of the older hatcheries and enlargement and improvement of the newer establishments. The work involved replacement of pipe lines or complete construction of new water-supply systems; construction, repair, and improvement of buildings; construction of ponds; installation of new equipment; and general landscaping. In some instances there was a 100-percent increase in the productive capacity of a station. The Public Works Administration funds were largely used for the purchase of materials, supplies, and equipment; while the labor, practically all from relief sources, was a contribution from the Works Progress Administration alletment.

The principal development of an entirely new nature was the construction of a pondfish hatchery at the Roy Inks Dam on the lower

Colorado River in Texas. The site was furnished by the Lower Colorado River Authority and the construction was supervised by the Bureau. It was financed by a portion of the P. W. A. allotment and by the assignment of N. Y. A. labor. At the close of the year this project was virtually completed and some of the ponds were stocked with fingerling bass.

Great improvements were effected at the Fort Worth station, where an additional tract of land was donated by the city of Fort Worth

and utilized for the development of additional ponds.

The Charlevoix, Mich., hatchery, which had been closed since 1933, was entirely rehabilitated and equipped for the rearing of lake trout

fingerling.

In several instances the State W. P. A. projects were in effect, also making possible additional improvements. An outstanding example of this method was at Guttenberg, Iowa, where initial work on a very large bass and pondfish hatchery within the Upper Mississippi River Wild Life and Fish Refuge was undertaken. Curtailment of the scope of the C. C. C. resulted in some restriction of the construction work prosecuted by this agency. A limited number of assignees were held at work at Lamar, Pa., but the C. C. C. development at the York Pond, N. H., station was terminated. However, it was possible to continue developments there by utilization of emergency funds allotted directly to the Bureau.

In addition to the improvements made possible by direct cash allotments to the Bureau, the Appropriation Act for 1939 carried the sum of \$155,000, provided for the construction of new hatcheries in Kansas, North Dakota, Minnesota, and Ohio. A suitable site was located at Valley City, N. Dak., and, at the close of the fiscal year, the hatchery was approximately 75 percent completed, although not in readiness for operation. Sites were selected at Hebron, Ohio, Farlington, Kans., and New London, Minn., but various difficulties were encountered in acquiring clear titles to these sites, with resultant delay in starting actual construction. At the close of the year, however, preparations were being made to initiate the construction phase at each of these locations. The funds appropriated for these hatcheries were continued available during the fiscal year 1940.

By means of funds allotted from the Public Works Administration and the Works Progress Administration, improvements were also made during the year to the technological byproducts laboratory building and the chemical laboratories in Seattle, Wash.

ALASKA FISHERIES SERVICE

ADMINISTRATION OF FISHERY LAWS AND REGULATIONS

Careful observations of the runs and escapement of salmon were made in all fishing districts, and regulations were modified as seemed desirable. In general, the salmon runs were satisfactory, and most of the changes in regulations during the season were relaxations to permit additional commercial fishing in specified localities. The Commissioner of Fisheries spent several weeks in Alaska inspecting the fishery and fur-seal activities.

Revised regulations, issued on February 11, to be effective in 1939 contained few changes of major importance. The salmon fishing

season was shortened in parts of southeast and central Alaska, and in some localities the season was extended slightly, in view of the satisfactory runs. In order to promote the use of claims for outlying areas that had previously been but little exploited, the limitation on the pack for the Seward-Katalla district as a whole was increased, while a limitation was placed on the output of certain well-known beds in the district. Some additional restrictions were placed on commercial fishing for herring and crabs.

Two 15-year leases of oyster bottoms in Alaska were executed during the fiscal year 1939 under the authority granted by the act of August 2, 1937, for the protection of oyster culture in Alaska. Liberal leasing terms have been established in order to encourage the

development of this industry.

Fourteen vessels of the Bureau, five speedboats, and a number of other small power boats were used in the patrol of the fishing grounds. The personnel identified with fishery-protective work numbered 209, including wardens, stream guards, weir operators, vessel crews, and biologists. Chartered airplane service was used to some extent to supplement the vessel patrol, and also for surveys of the spawning

grounds and transportation of officials to isolated districts.

Attention was given to the reclaiming of former spawning areas that had become inaccessible to the salmon by reason of accumulated débris from slides and windfalls. This work was largely incidental to the patrol of the fishing grounds. The destruction of predatory trout that feed upon salmon eggs and fry was continued in the Bristol Bay and Cook Inlet regions through funds supplied by the Territory and by local salmon packers. An appropriation of \$25,000 was made by the Territorial Legislature in 1939 to continue the improvement of salmon streams and the payment of bounty on predatory trout during the next 2 years.

Biological studies of the salmon and herring were continued, the work in connection with the former being extended to include a comprehensive investigation of the red-salmon fisheries of Bristol Bay. Further studies concerning the effect of predatory trout in reducing the numbers of young salmon were carried on in the Kodiak region. Weirs for counting the escapement of spawning salmon were

operated in 11 representative salmon streams.

PRODUCTS OF THE FISHERIES

Notwithstanding the fact that several plants stood idle because of prolonged labor negotiations in the spring and the consequent delay in preparation for the season's operations, the volume of fishery products in Alaska compared favorably with the average for recent years. An outstanding feature was the unusual abundance of red salmon in the Bristol Bay area, resulting in the largest catch ever recorded for that region.

The total output of Alaska fishery products in 1938 was 446,664,000 pounds, valued at \$42,870,000, as compared with 452,545,000 pounds, valued at \$51,743,000 in 1937. The estimated value of the 1938 catch to the fishermen was approximately \$12,040,000, or about \$2,198,000 less than in the preceding year. There were 28,084 persons employed in the various branches of the industry, as against 30,331 in 1937.

Salmon products comprised approximately 78 percent in quantity and 91 percent in value of the total output of the Alaska fisheries in 1938. Ninety-three percent of the salmon products consisted of canned salmon, the pack amounting to 6,807,000 cases, or 326,736,000 pounds, valued at \$36,637,000. Red salmon represented 37 percent and pinks 47 percent of the total pack of canned salmon, as against 32 percent and 54 percent, respectively, in 1937. As compared with the pack of the preceding year, the output of canned salmon in 1938 showed an increase of 2 percent in quantity but a decrease of nearly 18 percent in value. Ninety-eight canneries were operated, or 15 less than in 1937, and the number of persons employed in the salmon-canning industry dropped from 24,865 in 1937 to 22,280 in 1938.

Seventeen herring plants were operated, as compared with 20 in the previous year, and the quantity of herring products declined from the peak production of 1937, although continuing at a comparatively high level. Other fisheries in which there was a decreased production included the whale, shrimp, and crab industries. Only one whaling station was operated in Alaska in 1938. Halibut landings of the Alaska fleet showed a slight increase in volume, as did also cod, clam, and a few other minor fishery products.

ALASKA FUR-SEAL SERVICE

GENERAL ACTIVITIES

Sealing and foxing operations at the Pribilof Islands were carried on, as heretofore, by the natives under the supervision of a staff of 13 regular employees and a number of sealing assistants. Approximately 80 Aleutian natives also were employed during the summer in connection with sealing activities, and 23 skilled employees of the Fouke Fur Co. were at the islands for several weeks to assist in curing and packing the sealskins.

The byproducts plant on St. Paul Island was operated for the utilization of fur-seal carcasses. Products for the 1938 season amounted to 30,587 gallons of oil and 357,222 pounds of meal. These products, other than small quantities retained at the islands for fox feed, were shipped to Seattle, where the oil was sold for commercial use and the meal was transferred to the Division of Fish Culture for feeding fish at the batcheries

feeding fish at the hatcheries.

On St. George Island a warehouse and three new cottages for natives were built, and improved roads were extended about a mile. Considerable resurfacing of roads also was done there and on St. Paul Island. Four cabins and a powerhouse, as well as some new equipment, were added to the substation for sea-otter investigations and patrol in the western Aleutians.

Valuable cooperative service was rendered by the Navy Department in assibning the U. S. S. Vega to carry the annual shipment of supplies to the Pribilof Islands, and by the Coast Guard in patrolling waters of the North Pacific and Bering Sea for the protection of fur

seals and sea otters.

Delivery of 8,755 fur-seal skins, or 15 percent of the take on the Pribilof Islands in 1938, was made to an agent of the Canadian Government at Seattle. The Japanese Government, entitled to a like

number under the provisions of the fur-seal treaty of 1911, continued the practice of sharing in the proceeds of sale, rather than taking

actual delivery of the skins.

Two hundred and ten fur-seal skins taken by the Japanese Government on Robben Island in 1938 were allotted to the United States as its share under the treaty provisions and were shipped to the Department's selling agents at St. Louis, Mo., for processing and sale.

A new contract for the processing and sale of Government-owned fur-seal and other skins was entered into by the Acting Secretary of Commerce and the Fouke Fur Co., St. Louis, Mo., under date of June 9, 1939, covering sealskins taken in 1939 and the following season, and thereafter until the contract is terminated by either party.

SEAL HERD

The computed number of animals in the Pribilof Islands fur-seal herd on August 10, 1938, was 1,872,438, an increase of 33,319, or about 2 percent over the corresponding figure for the preceding year. This comparatively small increase is accounted for by the fact that it has been found necessary to apply higher mortality rates for animals in their first year at sea and to make adjustments accordingly in respect to certain age groups.

TAKE OF SEALSKINS

In the calendar year 1938 there were taken on the Pribilof Islands 58,364 fur-seal skins, of which 46,082 were from St. Paul Island and 12,282 from St. George Island. This was an increase of 3,184 over the total take in 1937. Insofar as possible, killings were confined to 3-year-old males. A suitable number of this age class was reserved for breeding stock.

SALE OF SEALSKINS

Two public auction sales of fur-seal skins were held at St. Louis in the fiscal year 1939. At the sale on October 10, 1938, there were sold 9,754 skins dyed black, 14,490 skins dyed safari brown, and 46 miscellaneous skins for a gross total of \$509,293.75. On May 22, 1939, 7,800 skins dyed black and 12,720 dyed safari brown brought a gross sum of \$344,338.75.

Sealskins sold at private sales under special authorization by the Secretary of Commerce consisted of 324 dyed black, 487 dyed safari brown, 1 partly processed, and 73 raw-salted skins, which brought a gross total of \$17,713. In all, 45,695 fur-seal skins were sold for the account of the Government in the fiscal year 1939, for a total gross

sum of \$871,345.50.

FOXES

The care of blue foxes on the Pribilof Islands is an important seasonal activity, requiring attention only during the winter months when sealing operations are at a minimum. During the 1938-39 season 219 blue and 5 white foxskins were taken on St. Paul Island and 799 blue and 6 white foxskins were taken on St. George Island, a total of 1,029. Suitable reserves for breeding purposes were made

on both islands. Eight hundred and forty-seven blue and 16 white foxskins, taken on the Pribilof Islands in the 1937-38 season, were sold at public auction in the fiscal year 1939. The blue foxskins brought \$16,452.50 and the white skins brought \$216, a total gross sum of \$16,668.50.

FUR-SEAL SKINS TAKEN BY NATIVES

The North Pacific Sealing Convention of July 7, 1911, provides that aborigines dwelling along the Pacific coast may take fur seals under restricted conditions. In 1938 Indians under the jurisdiction of the United States took 184 sealskins and Canadian Indians took 1,367 sealskins, which were duly authenticated by Government officials of the two countries.

FUR-SEAL PATROL

Vessels of the Coast Guard were again assigned by the Secretary of the Treasury to patrol waters of the North Pacific and Bering Sea for the protection of the fur seals and sea otters. One vessel of the Bureau of Fisheries also participated in the fur-seal patrol during the northward migration of the herd.

PROTECTION OF SEA OTTERS, WALRUSES, AND SEA LIONS

New regulations for the protection of walruses and sea lions were issued on June 29, 1939, extending the closed season on these animals until June 30, 1941, while continuing permission for their capture under certain specified conditions. The killing of sea otters is prohibited at all times.

PROPAGATION AND DISTRIBUTION OF FOOD AND GAME FISHES

The preliminary records of production for the hatcheries operated by the Division of Fish Culture show an output of 8,094,000,000 eggs. fry, and larger fish. With the 1938 production amounting to slightly over 8,121,000,000 it is evident that there was little variation in the scope and magnitude of the activities. Forty-six species were handled at the hatcheries and in the rescue fields. Among the individual species an increase was recorded for 16. As usual the greatest increase was shown with the commercial or semicommercial species. The Bureau initiated the propagation of Kentucky bass, which had not previously been handled at its hatcheries. No glut herring, carp, or humped-back salmon were handled at the hatcheries during the fiscal year 1939. The conduct of repair and improvement work rendered some of the fish-cultural facilities inoperative during the season with consequent curtailment of production of fish. The output of brooktrout eggs was unusually low because of the fact that a disease epidemic at the York Pond, N. H., station, the principal point of production for this species, necessitated a complete elimination of all stock on hand and reduced the distribution to negligible proportions. The production of fingerlings and large fish was 84,459,000, which presents a sharp drop in comparison with the previous year when 119,000,000 were handled. This, however, does not indicate any limitation upon the hatcheries' activities but is rather a reflection of the virtual cessation of rescue and salvage work in the Upper Mississippi River Wild Life and Fish Refuge, from which source the fingerlings of warm-water species have heretofore been obtained in large numbers. The number of unfilled applications for game species as submitted by private individuals and conservation organizations was, at the close of the year, as low as at any time within recent years.

PROPAGATION OF COMMERCIAL SPECIES

The three hatcheries in New England propagating commercial species of the inshore waters were operated with increased intensity with the result that there was a noticeable increase in the production of cod, haddock, and flatfish. Pollock were produced in reduced quantities and the output of lobster fry was approximately 50 percent of the previous year's record. However, by virtue of new experimental methods the young lobsters were reared to larger size before releasing, as a means of producing greater survival. Over 51/2 billion of the above-mentioned species were distributed as fertilized eggs on the spawning grounds. This is a byproduct recovery, since these eggs would otherwise be completely wasted in the marketing of the fish taken by the commercial fishermen. Propagation of mackerel was again resumed at the Woods Hole, Mass., station with an output of 11,000,000 fry. An outstanding development was the establishment by the Maine Department of Sea and Shore Fisheries of a large modern lobster-rearing unit on the grounds of the Federal hatchery at Boothbay Harbor, Maine. This establishment is operated by the State on a cooperative basis with the Bureau. There is assurance that this project will be of great significance in the future in conserving and building up the supply of lobsters, the mainstay of the inshore fisheries of the State.

Pacific salmon.—There was a worthwhile increase in the production of chinook salmon. This species is handled in two fields, the Columbia River and the Sacramento River, and the distribution was materially increased in both areas. This is especially gratifying in view of the fact that both runs have been threatened by the construction of large dams, and the 1939 figures for hatchery production indicate that there will be a satisfactory stock of salmon upon which to base future propagation activities which will serve to nullify the detrimental influences of dams. Absence of humped-back salmon in the records is merely a result of the so-called "off year" for this spe-Sockeye salmon are handled in the Puget Sound area and at Quinault, Wash. At the latter point the production is deliberately curtailed so as to permit the rearing of all of the fry produced to a larger size before distribution. The salmon hatcheries also included the propagation of steelhead trout, a preeminent game fish, within the scope of their work but failed to obtain a production equal to that of the previous year.

Anadromous species, Atlantic coast.—The second year of an intensive program of rehabilitation of the shad has shown an increase in the hatchery production of this species. Over 34 million fry were planted, in comparison with 26 million in 1938. No new propagating stations were operated and the increase is a direct result of larger runs and more intensive hatchery utilization of the potential egg supply. The shad stations on the Potomac River and at Edenton, N. C., also proagated other indigenous species, including the white

perch, yellow perch, and striped bass. These are handled somewhat as a side line since they are propagated during the inactive season for shad. The output of 1,797,000 striped bass fry in North Carolina represents a material increase and is in line with an effort to build up

this valuable species.

Commercial species, interior waters.—Inasmuch as the supply of buffalofish and carp appears adequate for economic needs the hatchery production of these forms was curtailed and no carp whatever were distributed. Several of the States in the Great Lakes area are opposed to any promiscuous propagation or distribution of carp and the Bureau has coordinated its work accordingly. As a consequence the present contribution to the commercial fisheries of the interior section was the propagation of whitefish, lake herring, and lake trout carried on at Put-in-Bay, Ohio; Duluth, Minn.; and Cape Vincent, N. Y. Production of pike perch at Put-in-Bay was brought up to 334,000,000, a noticeable increase over 1938. The aggregate production of whitefish at the Bureau's stations amounted to approximately 33,000,000, somewhat lower than the previous year. Lake trout production at a level of slightly over 2,000,000 reflects the difficulty of securing eggs of this species. A new policy was adopted in connection with the propagation of the lake trout, however, by the reopening of the Bureau's hatchery at Charlevoix, Mich., for the purpose of rearing the fish to the fingerling size before release. Several hundred thousand lake-trout fry were supplied by the Michigan Conservation Department and were being fed at the Charlevoix hatchery at the close of the year. The activities at the Put-in-Bay. Ohio. station were conducted jointly with the State of Ohio, as has been the case for several years. It is felt that the State is in a position to take full responsibility for this work and at the close of the year negotiations were under way whereby the hatchery property might be turned over to the State.

Game species.—Again the collection of black-spotted trout eggs at Yellowstone Park was materially increased, the collection of eggs approaching 40,000,000. There was a moderate drop in the production of the other species of game trout, and a noticeable increase in the production of largemouth and smallmouth bass, the distribution amounting to over 14,000,000. Of this total, approximately 9,000,000 represented the fingerling and larger sizes which are so eagerly sought for restocking the tremendous area in which these two species thrive. The yield of the lesser warm-water species, including the sunfish, crappie, rock bass, warmouth bass, catfish, etc., was greatly below the levels maintained previously. However, as indicated elsewhere, this is of little significance as far as stocking is concerned because of the fact that the millions released in previous years were largely replanted directly in the Mississippi River in the area where they were salvaged. There was a continuation of the program for acquiring more distribution trucks, and the handling of fish applications was systemized and organized so as to coordinate the planting with the corresponding activities of the States. More and more of the game fish from Federal hatcheries are being utilized in stocking Federal lands, particularly in national forests, reclamation reserves, Indian reservations, and tracts which have been acquired in the land-utilization program.

The Bureau again made an allotment of rainbow trout eggs to Puerto Rico in continuation of the program for developing trout fishing in that Territory.

RESCUE OPERATIONS

The virtual completion of the 9-foot channel in the upper Mississippi River brought to a practical close the practice of salvaging fish in the overflowed areas and sloughs, which development has been predicted by the Bureau. There were handled in this activity only 2,800 fish of all species in comparison with the 40 to 50 million which were seined and returned to the river in the past. The Bureau, however, has proceeded with the construction of propagating ponds in the Refuge, particularly at Genoa, Wis., and Guttenberg, Iowa. The yield of game fish, especially bass, from these ponds has been most surprising and there is ample evidence of a continuing supply of bass and sunfish if the program of construction can be continued.

FISHERY INDUSTRIES

ECONOMIC AND MARKETING INVESTIGATIONS

Surplus fish situation.—The holdings of frozen, cured, and canned fishery products in the United States in the spring of 1939 amounted to about 172,000,000 pounds, according to a study of the surplus fish situation. This represents about 5,600,000 pounds more than normal holdings.

Survey of retail marketing of fish and shellfish.—The field work of a survey of retail marketing of fish in about 50 representative cities east of the Mississippi River was completed late in the fiscal year 1939. The results of the survey will be tabulated and analyzed to determine the factors which lead to the most favorable response from the public and to establish criteria which may guide retailers toward those practices which are most successful or promising.

Commercial fisheries of the world.—On the basis of the most recent available data, the world's annual commercial catch of fishery commodities amounts to about 33,600,000.000 pounds, valued at approximately \$740,000,000. The United States, including Alaska, ranks first in the value of annual yield and is exceeded only by Japan in relume

Cod fisheries off the east coast of North America.—In 1935, which is the most recent year for which complete statistics are available, the catch of cod off the east coast of North America by Canadian United States, French, and Portuguese fishermen, amounted to 1,109,000,000 pounds, as compared with an average annual catch of 1,108,000,000 pounds for the 10-year period from 1926 to 1935, inclusive, and 1,169,000,000 pounds for the preceding 10-year period. The most important country in the volume of its catch of cod in this area is Newfoundland, which took an annual average of 495,000,000 pounds during the period from 1931 to 1935. Following in order of the importance of their annual catches were Canada, France, the United States, and Portugal.

Cooperative marketing.—During 1938 work was continued on the collection of data relating to fishermen's cooperatives and other fishermen's organizations in this country and abroad. Appeals for aid

in organization of cooperatives have been received from many sections of the country and such assistance has been rendered as has been possible with the limited staff and funds available for this work. Arrangements have been completed to enlist the aid of statistical and marketing agents of the Bureau, who visit virtually all the fishing areas of the United States each year, to assist in keeping the Bureau's data on fishermen's organizations current.

STATISTICAL INVESTIGATIONS

FISHERIES OF THE UNITED STATES, CALENDAR YEAR 1937

New England States.—The commercial fisheries of Maine, New Hampshire, Massachusetts, Rhode Island, and Connecticut in 1937 gave employment to 19,624 fishermen who took 670,864,000 pounds of fishery products, valued at \$19,937,000. This is an increase of 2 percent in volume and 11 percent in value as compared with 1935 when the most recent previous survey of the total catch was made. Landings by United States fishing vessels at Boston and Gloucester, Mass., and Portland, Maine, in 1937, amounted to 387,960,000 pounds, valued at \$9,790,000—a decrease of 6 percent in volume and 12 percent in value as compared with 1936.

Middle Atlantic States.—During 1937 the commercial fisheries of New York, New Jersey, Pennsylvania, and Delaware gave employment to 7,720 fishermen. Their catch amounted to 264,652,000 pounds, valued at \$7,896,000—a decrease of 5 percent in volume but an increase of 23 percent in value as compared with the catch in 1935 when the preceding complete survey of the catch was made. A survey of the Hudson River shad fishery for 1937 showed that 613 fishermen took 2,732,000 pounds of shad, valued at \$213,000—an increase of 11 percent in volume and 25 percent in value as compared with the catch

in the previous year.

Chesapeake Bay States.—In 1937 the commercial fisheries of Maryland and Virginia employed 16,529 fishermen. Their catch amounted to 292,244,000 pounds, valued at \$6,361,000—a decrease of 7 percent in volume and 2 percent in value as compared with the previous year.

South Atlantic and Gulf States.—The commercial fisheries of North Carolina, South Carolina, Georgia, Florida, Alabama, Mississippi, Louisiana, and Texas gave employment to 30,244 fishermen in 1937. Their catch amounted to 546,751,000 pounds, valued at \$14,226,000 a decrease of 2 percent in volume but an increase of 5 percent in value

as compared with the previous year.

Pacific Coast States.—During 1937 the commercial fisheries of Washington, Oregon, and California gave employment to 21,555 fishermen, whose catch amounted to 1,576,877,000 pounds, valued at \$28,776,000. This is a decrease of 18 percent in the volume but an increase of 16 percent in the value of the catch as compared with the previous year. The total catch of halibut by United States and Canadian vessels in 1937 amounted to 48,659,000 pounds, valued at \$3,828,000—an increase of 1 percent in volume and 6 percent in value as compared with the catch in the preceding year.

Lake States.—In 1937 the commercial fisheries of the United States and Canada, in the Great Lakes and international lakes of northern Minnesota (Lakes Ontario, Erie, Huron, Michigan, and Superior,

Namakan and Rainy Lakes, and Lake of the Woods), yielded 116,064,000 pounds of fishery products. Of this amount, United States fishermen took 83,958,000 pounds, valued at \$6,033,000—a decrease of 11 percent in volume and 6 percent in value as compared with the catch in the previous year. The Lakes fisheries of the United States gave employment to 6,418 fishermen in 1937.

Mississippi River and tributaries.—Complete data on the fisheries of the Mississippi River and its tributaries were not obtained for 1937. The catch of Lakes Pepin and Keokuk and the Mississippi River between the two lakes in 1937 amounted to 5,585,000 pounds, valued at \$226,000—a decrease of 32 percent in volume and 40 percent in value as compared with the catch in these waters during 1936.

MANUFACTURED PRODUCTS OF THE UNITED STATES AND ALASKA, CALENDAR YEAR 1937

Fresh and frozen packaged fishery products.—In 1937 the domestic production of fresh and frozen packaged fishery products amounted to 201,803,000 pounds, valued at \$27,678,000. Important commodities in this group were fresh-shucked oysters, 6,644,000 gallons, valued at \$9,081,000; packaged haddock, 30,187,000 pounds, valued at \$4,162,000; and fresh-cooked crab meat, 8,300,000 pounds, valued at \$2,822,000.

Frozen products.—The production of frozen fishery products in 1937 amounted to 168,224,000 pounds, estimated to be valued at \$14,600,000. The volume of the production was 6 percent less than in 1936. The principal items frozen were groundfish, whiting, salmon, halibut, and rosefish.

Cured products.—The production of cured fishery products, based on surveys for 1937 in all sections except the Mississippi River, and for 1931 in that area, amounted to 104,339,000 pounds, valued at \$15,636,000. Important products in this group were smoked and kippered salmon, 12,173,000 pounds, valued at \$3,515,000; salted cod, 19,857,000 pounds, valued at \$2,379,000; and mild-cured salmon, 9,615,000 pounds, valued at \$1,863,000.

Canned fishery products.—In 1937 the production of canned fishery products amounted to 742,197,000 pounds, valued at \$105,175,000—a decrease of 7 percent in volume but an increase of 11 percent in value, as compared with 1936. Canned salmon was the most important item, accounting for 362,642,000 pounds, valued at \$52,924,000. Other leading canned fishery products were tuna and tunalike fishes, sardines, shrimp, mackerel, clam products, and oysters.

Byproducts.—The production of fishery byproducts in 1937 was valued at \$36,804,000—an increase of 17 percent as compared with the previous year. The principal products in this group were marine-animal oils and meals and aquatic shell products.

FISHERY MARKET NEWS SERVICE

The past year has been one of intensive activity in the development of the Fishery Market News Service and in the opening of new offices. Field offices for the daily collection and dissemination of fishery market news are now operating in New York, N. Y.; Boston, Mass.; Chicago, Ill.; Seattle, Wash.; and Jacksonville, Fla. In addition to these offices for the preparation and dissemination of daily reports,

the service also operates numerous news-reporting activities in important fish-producing areas along our coasts. These reporting activities make possible the inclusion of a much wider coverage of news in the daily reports of our field offices than would otherwise be possible. Periodic market news reports also are prepared and disseminated from the Washington office. These include summarized data made available through the daily and monthly reports of the field offices as well as articles relating to the commercial fisheries and other related information.

TECHNOLOGICAL INVESTIGATIONS

Preservation of fishery products for food.—During 1938 projects in this field included studies of rancidity in fish, of lactic acid as a possible index of decomposition in frozen fish, of identification of canned salmon, of changes in the composition of pink salmon, of the composition of commercial species of fish taken on the Pacific coast.

and the canning of aquatic products.

Of particular interest has been the work on lactic acid as a possible index of decomposition in frozen fish. It is known that lactic acid rises to a maximum content in fish muscle during the rigor of death. It has also been shown that the alkaline reaction of fish muscle and the accompanying onset of spoilage of the fish follows after the loss of muscular rigor. Since spoilage occurs after the lactic acid content of the fish muscle reaches a maximum, the determination of lactic acid in fish flesh before and during a period of cold storage is of value in obtaining direct knowledge of the processes of decom-

position of fish.

Information has been obtained regarding the changes in the chemical composition of pink salmon accompanying the pronounced physical change during their spawning migration and while in the commercial fishery. Additional data have been collected in connection with the development of a means for identifying the various species of salmon after canning. A survey has been undertaken to determine the chemical composition of the principal food fish of the Pacific coast, and the wastage occurring during their preparation for market. Studies were continued to determine the effectiveness of certain natural antioxidants in preventing rancidity in preserved fishery products and an attempt is being made to develop a simple and accurate method for measuring oxidative deterioration in fatty fish.

Bacteriological studies.—During the past year important bacteriological problems were studies of ultraviolet rays in killing bacteria, studies in the handling of fresh oysters, and studies of methods of

preparing crab meat.

The studies in the handling of fresh oysters revealed that there is a definite relation between the pH in oysters and the bacterial count. The experiments showed that the bacterial flora changes with the acidity of the oysters and the bacterial count rises as a result of the increased acidity of the oysters. It was further discovered that excessive washing of oysters with fresh water caused a loss of mineral content.

At the request of several members of the crab-meat industry, the Bureau assigned a chemist and a bacteriologist to investigate possible measures designed to improve the quality of their product. This investigation included a survey of the crab-meat packing plants with

a view to making recommendations as to improved methods of handling and packing for shipment which would assure the public a higher quality product. Tentative recommendations were made to the crab-meat packers pending the issuance of a completed report.

Pharmacological studies.—As indicated in previous years, the role of minerals in nutrition has become increasingly important. Fishery products are considered to be an excellent source of minerals in quantity and variety, and a better understanding of the physiological effects of these minerals on the animal organism is necessary. During 1938 the Bureau's technologists completed a study of the chemical and pharmacological aspects of fluorine in fishery products. No toxic symptoms were observed when the fluorine in the diet came from salmon or mackerel.

Nutritive value of fishery products.—During 1938 investigations in this field included a study of the chemical composition and nutritive value of fish proteins, the vitamin content of fishery products, a study of sodium alginate (produced from sea kelp) as a stabilizer in products of the dairy industry, and a cooperative study of kelp meal in animal feeding at the dairy department of the University of Maryland and of the Maryland State Agricultural Experiment Sta-

tion, College Park, Md.

The studies of the mineral constituents of fishery products showed that fish fillets are about equal to the muscle cuts of beef in mineral content, except that the fish greatly exceeds the meat in iodine content; that canned salmon contains about 15 times as much calcium, almost twice as much phosphorus, 20 times as much iodine, and approximately equal quantities of other minerals as beef round; and that oysters, shrimp, and crab meat contain approximately half as much calcium, more than 5 times as much magnesium, and more phosphorus than an equal quantity of milk. In addition, these shellfish are a particularly good source of iron, copper, and iodine.

The results of the studies on the chemical composition and nutritive value of fish proteins showed that, by using an arbitrary factor of 100, the proteins of the following fish and shellfish fell into the following groups according to relative growth-promoting value, as compared to beef at a factor of 63: Oysters, 100; pilchard, red snapper, shrimp, and Boston mackerel, 90; and shad, cod, croaker, and

silver salmon, 80.

The results of the studies on sodium alginate showed that this product is an excellent mechanical stabilizer for use in food products, due to its chemical and physical properties and high viscosity value.

Preservation of fishery byproducts.—During the year data have been obtained regarding specific problems of salmon cannery waste utilization. These include investigation of the suitability of small-unit operations for canneries whose outputs are too small to warrant installation of standard fish-meal equipment, the preparation of edible salmon oils, the preparation of dehydrated protein and vitamin concentrates, and in the case of large canneries having short operating seasons, the chemical preservation of waste for subsequent reduction and the conversion of waste into new types of products as a result of chemical treatment. A survey was undertaken to determine the potential vitamin value of the livers and viscera of the principal food fish taken commercially on the Pacific coast. In cooperation with the Division of Fish Culture and the University of Washington

School of Fisheries, information was obtained which helps to clarify the steps in preparation responsible for improving the nutritional properties of fish meal for fish feeding and which suggest less costly processes of manufacture. Also, studies were made which indicate the possibility of materially reducing the danger of spontaneous heating of fish meal, a difficulty which now causes the industry great inconvenience and considerable financial loss.

BIOLOGICAL FISHERY INVESTIGATIONS

INVESTIGATIONS OF COMMERCIAL FISHES

North Atlantic fishery investigations.- In the offshore fisheries of New England, analysis of extensive data collected during the course of the haddock investigation has thrown considerable light on the changes in the abundance of this species and has suggested a plan for the stabilization of yield. Years of poor survival are either years in which large haddock are especially abundant, offering serious competition for food, or years when the stock of adults has been so reduced as to furnish insufficient spawners. The most favorable level was approximately that which prevailed in 1922 to 1924, 1929, and 1936. The course of the natural cycles of abundance may be seriously interfered with if a period of intensive fishing happens to coincide with a period of poor survival of the young. The recent marked decline in the abundance of haddock, which has been evident both on Georges and the Nova Scotian Banks has been shown to be the result of such a combination of circumstances. It is indicated, therefore, that by holding the population at the optimum level by regulation of the fishing intensity, it would be possible to sustain the yield at a productive level.

Data collected during the year on the age composition of the catch revealed an increasing dependence on the young or "scrod" haddock, a trend which is regarded as prejudicial to the interests of the fishery, inasmuch as these fish are growing rapidly and would be of consider-

ably greater value if allowed at least 1 more year's growth.

The catch records and biological data collected during the 1937 mackerel season, a year of extremely low production, were subjected to analysis during the year. The composition of the mackerel population differed markedly from previous years in that no year class or classes dominated the fishery. With the exception of the 1932 class, year classes following 1929 were present in better than 5 percent strength each. Inasmuch as a study of lightship temperature records revealed that water temperatures in the western part of the Gulf of Maine ran higher than the average for the previous 10 years, it is suspected that hydrographic conditions affected the distribution of mackerel and were an important factor in the low catch.

The catch for the 1938 season was almost double that of 1937, but the early season landings for 1939 sank to a lower level than those for the corresponding period of 1937. Biological data show that the mackerel spawned in 1937, a group that was expected to contribute much to the fishery, as 2-year-old fish were virtually unrepresented in 1939. Because pound-net fishermen inshore were reported to be making good catches, an investigation of the relation between the catch by semers offshore and that of the pound nets was begun early in the 1939 sea-

son to determine to what extent changes in the offshore catch may

represent merely changes in the distribution of mackerel.

During the fiscal year 1938 a study was undertaken to determine whether a decline in abundance of flounders is in progress in the North Atlantic area. In order to interpret fluctuations in abundance, it was necessary to develop techniques for determining age and growth, the existence of separate races within the population, and the extent of migrations.

Owing to the increased utilization of redfish, flounders, and other species of groundfish in addition to haddock, an investigation of the abundance of such fishes was begun during 1938. The central problem is to assess total catch, fishing effort, and abundance in order to determine for each species whether it has already reached the point where an increase in yield will give a larger production only with

detriment to future supplies.

As a result of cooperation between the Bureau of Fisheries and the State of Maine, an investigation to test new methods of rearing lobsters, to determine the relative effectiveness of artificial and natural propagation, and to ascertain the condition of the lobster fishery on the coast of Maine has been added to other scientific fishery investigations being conducted in the New England area. The State has constructed a lobster-rearing plant adjacent to the Bureau hatchery at Boothbay Harbor, with facilities for carrying on experimental work, and has assigned funds for the employment of a biologist. Experiments with larval lobsters and tagging of adults were begun during the spring of 1939.

Middle and South Atlantic fishery investigations.—At the request of the New York State Conservation Department, the Bureau participated in a biological survey of the marine fisheries of Long Island, acting principally in an advisory capacity. The survey was undertaken to provide a basis for improving or maintaining good fishing wherever the supply is controllable and to determine by a census of fishing activities the recreational and commercial value of the marine district of Long Island. Definite recommendations for the conservation of several species and for additional study have been included

in a report to be published by the State.

Evidence continued to accumulate which indicated an inadequate spawning escapement as the principal cause of the decline in abundance of shad along the Atlantic coast. Much of the field work of this investigation has been directed toward comparison of the spawning escapement in the Hudson, where complete recovery of abundance has occurred, with the escapement in other rivers which are still severely depleted. The principal methods of study are tagging experiments, designed to estimate fishing intensity from the percentage of tags recovered, and studies of scales intended to estimate the percentage escapement from the percentage of scales bearing spawning marks.

Prior to recommending measures to insure an adequate number of spawners in the various coastal rivers, it was necessary to determine whether shad return to spawn in their native rivers or whether, as many fishermen believe, there are extensive migrations. A direct attack on this problem has been made by tagging. Results of tagging experiments in North Carolina, the Chesapeake Bay, and the

Hudson indicate that the great majority of shad return to the same river year after year. Additional data on this point are being gathered by extensive analysis of the racial characteristics of shad from the different rivers.

Because of the importance of reproduction in shad conservation a careful ecological study of the early life history is being made in southern rivers. In 1938 intensive work was done in the Edisto and

in 1939 these studies were extended to other rivers.

Shrimp investigations.—Studies of the shrimp fishery consisted of several cruises to assess available supplies in the offshore waters of the Gulf of Mexico, a continuation of tagging experiments to determine the seasonal migrations of shrimp along both the Atlantic and Gulf coasts, and ecological studies of the relationship between environmental changes and the distribution of shrimp along the Texas coast.

As a result of a cruise of the *Pelican* along the Louisiana and Texas coasts in January and February, the presence of shrimp off the Louisiana coast in concentrations sufficient to warrant commercial exploitation was confirmed. No large concentrations of commercial shrimp were found off the Texas coast. In a later cruise a similar lack of commercial shrimp was observed off the coasts of Alabama and Florida between Mobile Bay and Apalachee Bay.

Tagging of shrimp on the Atlantic coast from Cape Canaveral to St. Augustine, where the bulk of the South Atlantic coastal shrimp congregate for the winter, gave evidence of a return movement at least as far as 250 miles northward. Other tagging experiments indicated that the small shrimp do not engage in coastwise migra-

tions as extensively as do the larger sizes.

In cooperation with the Texas Game, Fish, and Oyster Commission, a program of hydrographic surveys and experimental trawling was instituted in Aransas Bay to determine the extent to which hydrographic factors may control the distribution of shrimp and day-to-

day fluctuations in the catch.

North Pacific and Alaska fishery investigations.—Commercial fishery investigations in northern Pacific waters form the basis of recommendations for the management and conservation of the salmon runs in the rivers of the Northwestern Coastal States. They are also concerned with maintaining at a productive level the salmon and herring fisheries of Alaska, over which the Federal Government has

regulatory power.

The activities of the Columbia River staff have centered about the problem created by the erection of Grand Coulee Dam, blocking that portion of the Columbia River salmon run that normally spawns in tributaries of the upper Columbia. Salvage operations were begun in 1939. The runs are being trapped at Rock Island Dam, 150 miles downstream, and transferred in specially constructed trucks to tributaries between Rock Island and Grand Coulee Dams. It is hoped that the fish will spawn in these tributaries, and that their progeny will later return to them. If the plan yields the anticipated results, the entire run of upper Columbia fish will be transferred to tributaries below Grand Coulee within a period of 5 years, or the life cycle of a salmon.

At the beginning of the fiscal year 1939 Congress made funds available to the Bureau of Fisheries for a large-scale study of the factors that control the salmon populations of Bristol Bay in order that a sound and comprehensive system of management might be applied. With the cooperation of the Coast Guard, extensive hydrographic observations were conducted in the summers of 1938 and 1939. Biological observations were made also to discover the schooling habits of the fish far offshore, the abundance and distribution of food animals, and the migratory habits of the salmon in approaching the coast from these offshore feeding grounds. Correlated with these oceanographic studies, investigations of the life cycle of the salmon in the five major watersheds of this area are under way. These include detailed population studies of the spawning runs, surveys of spawning grounds, and measurement of the mortality of the young in fresh water. This investigation is planned to cover a 5-year period, or the normal life cycle of the red salmon.

Studies of the returns to be expected from any given escapements of spawning salmon were continued in the Karluk watershed. Further evidence was secured that variations in the ratio of returns to escapement are mainly due to conditions existing in the fresh-water environment. To determine the role of the predatory Dolly Varden trout in reducing the number of young red salmon, the migratory habits and biological characteristics of the populations of trout have been investigated through the tagging of large numbers of these fish.

In areas where the migration routes of salmon pass through commercial fishing areas to a number of different streams, the 50-percent escapement required by law cannot be assured unless the exact routes of the salmon and their distribution on the spawning grounds are determined. Tagging experiments were conducted during the 1938 and 1939 seasons to trace the migration routes of pink salmon passing through Lower Chatham Strait. The two experiments will provide information covering the routes of migration of both the odd-and even-year pink salmon runs.

The usual population studies to determine the size of the pink-salmon runs and the proportion of males and females were conducted at Little Port Walter. The construction of a permanent dam and counting weir, which was in operation during the 1939 season, now permits an accurate count of seaward-migrating young as well as upstream migrants, so that the returns from a known number of spawners may be determined with greater accuracy than heretofore. Changes in the time of appearance of the pink salmon runs are being closely analyzed so that any necessary curtailment of the fishery may be effected in time to allow an adequate escapement to the spawning grounds.

As an aid to rebuilding the runs of coho salmon in Puget Sound, studies have been carried on over a period of years to determine the age at which hatchery-reared fry may be released most advantageously. A series of marking experiments for this purpose was concluded in 1938. Biological studies of the size and age composition of the population were made by taking samples of the commercial catch and of the fish on the spawning grounds.

Studies of the age composition of the herring population of southeastern Alaska were responsible for demonstrating that this stock has declined to a dangerously low level and that curtailment of fishing is necessary. The decline has been caused by the virtual failure of three successive broods, those of 1932, 1933, and 1934, combined with excessive fishing. Closure of the Cape Ommaney area was recommended until the population shows definite signs of recovery. The fishery of the Prince William Sound and Kodiak areas continued at a high level of abundance, but since considerable expansion is contemplated, a close watch must be maintained to avoid over-exploitation.

Collection, tabulation, and analysis of the daily catch records from the various types of fishing gear operated by the salmon fishing industry in Alaska have been continued. Indexes of abundance derived from these data are an important basis of recommendations for

changes in the fishing regulations.

Pilchard investigations.—Although biologists of the Pacific Coast States have already collected a considerable body of information bearing on the migrations, spawning, and age and growth of the pilchard, the basic problem remaining for solution is the determination of the optimum level of catch below which the stock would go to waste through underutilization, above which it would become reduced to commercial unimportance through overexploitation. To provide a basis for determining this level, the staff conducted studies dealing with the determination of abundance, age, and reproductive success, and with the importance of intermigration.

The use of aerial observers in gaging abundance was tested but rejected as unsatisfactory. Changes in relative abundance are therefore being determined by statistical analysis of the commercial catch

records over a period of years.

To discover how much the stock is reduced by fishing it is necessary to determine the ages of the fish making up the population each year, thus learning the relative abundance of the individual broods of previous years and how fast they are removed by fishing and by natural mortality. Age determination is being attempted by interpreting marks in scales and otoliths, by observing the growth of young pilchards, and by identifying modes in frequency distributions of the adult population.

During the spring of 1939 several cruises were made in the spawning and nursery grounds, quantitative samples of the young pilchards being taken. These cruises were made possible by the cooperation of the Scripps Institution of Oceanography, which furnished the vessel E. W. Scripps. When the surveys are completed, it is hoped that light may be thrown on the distribution and abundance of eggs and young, as well as on the effect of oceanic conditions on the

success of spawning.

To determine whether the pilchard stock in northern waters is self-perpetuating or is maintained by migrations from other areas, techniques are being developed for appraising the contributions from various spawning areas through study of the sculpturing on the scales. If the method proves valid, it will aid in determining how much fishing in specific areas affects the stock in other areas.

Great Lakes fishery investigations.—A state of critical depletion continues to exist among the more valuable commercial species of the Great Lakes. The extent of this depletion is apparent from

comparisons of present-day production of certain species with yields of earlier years. In Lake Michigan, for example, production of wall-eyed pike, lake herring, lake trout, whitefish, and yellow perch varies from 43 to 62 percent of normal. Production of Lake Superior whitefish is only 10 percent of normal. In Lake Huron production of perch and chubs is 44 and 36 percent, respectively, of normal. In Lake Erie production of nearly all important commercial species is on the decline, and total production of Lake Ontario is only 10 percent of normal.

Members of the Great Lakes staff cooperated actively with State and Federal officials and with sport and commercial fishermen, participating in an advisory capacity in 19 meetings and conferences in which Great Lakes fisheries problems were under consideration and assisting State conservation officials in the drafting of fisheries

regulations.

At the request of the Office of Indian Affairs of the Department of the Interior, a survey was made of the fisheries of Upper and Lower Red Lakes in Minnesota to settle various controversies concerning the regulation of the commercial gill-net fishery. Recommendations for the management of the fishery are being submitted.

The report of the International Fact-Finding Commission on Lake Champlain was largely completed. The report will contain a discussion of the fisheries controversies, a tabulation and analysis of all available information concerning commercial fishing and angling, descriptions of the natural history of the various species, a critical historical review of the artificial propagation of wall-eyed pike and yellow perch, and recommendations for the regulation of the commercial and sport fisheries of the lake.

Age and growth studies of the whitefish of Lake Huron and Lake Champlain were completed for publication, and life-history studies

of the yellow perch were continued.

AQUICULTURAL INVESTIGATIONS

The work of the aquicultural investigations continued along three principal lines: The development of means to obtain the maximum production of food and game fishes consistent with environmental conditions, the improvement of methods of artificially propagating and rearing fish, and the control of fish parasites and diseases.

Investigations were conducted in trout waters to obtain definite information on the annual drain to which the trout population is subjected by anglers and the value of artificial stocking in maintaining a stable fish population. Such studies were conducted through the operation of test waters in Vermont; experimental stocking of streams in the Pisgah National Forest where fishing is closely supervised and an accurate check on returns may be obtained; and the operation of the Convict Creek experimental stream in California. These studies have demonstrated that in some situations natural propagation is superior to artificial in maintaining a stock of trout under adverse conditions and have emphasized the necessity of regulating planting operations in accordance with the amount of natural food present in the streams.

Feeding experiments with fingerling, yearling, and adult trout were carried out at the Leetown, W. Va., and Pittsford, Vt., stations to determine the effect on growth, mortality, and egg production of dry meals fed at different levels and in different combinations. One of the most striking results was the marked increase in growth following the addition of cod liver oil to a diet composed of sheep liver and whitefish meal. Experiments with broad fish showed considerable variation in the hatchability of eggs from fish on different diets.

During the year a regional biologist was appointed to resume fish management work in the Intermountain Region. In this area fishing intensity is increasing rapidly and many of the streams are unable to maintain a sufficient fish population to meet demands. In addition to overfishing, adverse changes in the streams and lakes are important factors in the general decline. Among such changes might be cited silting resulting from overgrazing, hydroelectric and irrigation projects that interfere with normal migrations, and fluctuations of water level in artificial lakes. Management plans have been worked out for several waters showing possibilities of early

improvement of fishery resources.

The staff of the California trout investigations has been engaged in determining the number of salmon and the extent of spawning streams that will be blocked by the completion of the Shasta Dam on the Sacramento River. The estimates of the 1938 fall run combined with the counts of the 1939 spring run fish indicate that approximately 25,000 salmon a year will ultimately have to be handled in the salvage operations. Pending the completion of engineering surveys to determine the feasibility of certain alternative features of the plan, a tentative program has been drafted which calls for a combination of artificial propagation and provision of areas for natural spawning below the dam.

Field work in bass streams was designed to measure the extent and efficiency of natural propagation and the effect of intensive fishing on the bass population. An important result of these studies was the finding that even in heavily fished waters there is little danger of serious depletion of bass if adequate spawning facilities are available. However, intensive fishing frequently leaves excessive numbers of small bass, with consequent reduction in the abundance of forage fishes. It is apparent that the remedy is to build up the food supply and that stocking with young will only serve to intensify the unbalanced condition. Programs for the effective management

of bass in ponds and lakes are being developed in Florida.

Facilities for the experimental study of fish diseases were greatly increased during the year with the enlargement of the field laboratory at the Quilcene, Wash., hatchery, and the provision of a second experimental laboratory through the cooperation of the University of Washington. Studies of various disinfectants used in the prevention and treatment of disease were continued to determine the maximum nontoxic concentrations that the fish could withstand. Studies of common bass parasites, believed to be an important factor in the mortality of the young, were carried on at Leetown, W. Va. The Disease Service continued to aid Federal, State, and private fishculturists in the diagnosis of hatchery disease.

POLLUTION INVESTIGATIONS

Field and laboratory studies have been continued over a wide area of the country for the purpose of analyzing stream and hatchery waters from the standpoint of their suitability for various types of fishes and of determining the harmful actions of specific pollutants. Methods of determining the physiological condition of the fish them-

selves have been markedly improved.

Many of the findings of the past year are of considerable interest and importance. For example, it has been found that arsenicals and other materials commonly used as mosquito larvacides impair the growth and nutrition of fishes even though used in very small quantities, and may also build up serious hazards of lethal poisoning. It has also been demonstrated that small quantities of many substances, normally present or introduced into streams and lakes, may have a cumulative effect over a period of time that is even more detrimental to fish life than many more obvious pollutants. Certain minerals found in small quantities in various western streams and several inorganic salts that are common in southern and western waters exert this type of cumulative action.

Problems arising from the concentration of minerals and other compounds hazardous to fish and other aquatic life in impounded waters have been investigated at Elephant Butte Reservoir, N. Mex., and

Lake Mead, Nev.

Acute pollution problems were investigated during the year in Florida, South Carolina, North Carolina, Minnesota, Idaho, Montana, Oregon, and Mississippi. Specific types of industrial pollution studied include that produced by paper mills, phosphate mines, and copper, lead, zinc, and placer gold mining operations.

CONSTRUCTION OF FISH-PROTECTIVE WORKS

A section on hydraulics has now been established under the supervision of the Division of Scientific Inquiry, with an experienced engineer for the design of fish-protection facilities. During the year the engineer assisted in designing and supervising the installation of fish screens being constructed with the aid of P. W. A. and W. P. A. funds on certain Federal power and irrigation projects in the Northwest. Important consulting services on screens and ladders were also afforded to other agencies.

SHELLFISH INVESTIGATIONS

Scientific investigations have been directed toward increasing the cultivation of oysters, improving the quality of oyster meat, and

standardizing the raw and canned product.

In the Long Island Sound area, where the collection of a good crop of seed oysters is of paramount importance to the industry, regular bulletins were issued during both the 1938 and 1939 seasons advising oystermen when spawning and setting might be expected. To aid in protecting valuable beds from starfish, surveys of the distribution of this oyster enemy were made and the results communicated to oystermen, permitting more efficient eradication.

On the south Atlantic coast, although generally favorable conditions for growth are found, some beds are badly overcrowded. Experiments are being conducted to develop a method of protecting seed oysters from the attachment of larval oysters, barnacles, etc., so that they may be grown to marketable size as single individuals of good quality.

Experimental oyster beds have also been established in South Carolina to develop methods of cultivation suitable for small oyster farms, from 2 to 10 acres in extent, to be leased and operated by the tidewater residents. The program differs from previous experiments in presupposing that capital requirements will be at a minimum and that materials, equipment, and supplies will be obtained or produced by the labor of the cycler farmer bimself.

by the labor of the oyster farmer himself.

At the Pensacola, Fla., laboratory an experimental oyster farm is being established to determine rates of growth and fattening, productivity annually per unit of bottom, and costs of production. The results will be compared with those of similar projects conducted on the Atlantic coast. A program of oyster planting and of rehabilitation of exhausted natural beds is also being conducted from this laboratory.

Investigations carried out at the Yorktown laboratory demonstrated that pollution of the river by pulp-mill wastes has brought the decline of the oyster fisheries. During the past year intensive chemical studies were carried on for the purpose of determining the particular chemical or chemicals in the pulp-mill effluents which are responsible for the altered physiology of oysters. An attempt will then be made to find a means of eliminating the harmful substances.

Studies of the physiology of the oyster carried out at Woods Hole, Mass., included investigations of the phenomenon of sex reversal in adult oysters, experiments on the time of survival of eggs and sperm, and a study of respiration in relation to the carbohydrate metabolism of the oyster and the accumulation of elements which are important food constituents of oyster meat.

LAW ENFORCEMENT DIVISION

The act of July 2, 1931, the Federal Black Bass Law regulating interstate commerce in black bass, is administered by this Division; also certain parts of the Whaling Treaty Act of May 1, 1936, giving effect to the various international treaties for the protection of whales. The Division also maintains an angler's service, and issues

permits to take bait fish in the District of Columbia.

The Federal black bass law.—The personnel and methods of enforcement remain the same as last year. Owing to insufficient personnel, no particular effort has been made to carry on the work west of the Rocky Mountains, where salmon and trout predominate. Reports of illegal interstate shipments of black bass have been investigated, producing evidence of violations of both State and Federal laws. A number of these cases have been turned over to the States for prosecution in State courts, as such action generally produces quick and effective results. Two cases of illegal interstate shipments of black bass by trucks were successfully prosecuted during the year, a fine of \$100 and 1 day in the custody of the U. S. Marshal being

assessed in each case. The defendant in one of these cases remained in jail approximately 3 months previous to trial, being unable to

furnish the required bond.

Improvements in State laws protecting black bass have been continued in accordance with the Bureau's recommendations for adequate protection. Thirty-nine States now prohibit the sale of black bass at all times, regardless of where taken, and all but four States provide a closed season on these game fish during at least a part of the spawning period. The States have cooperated 100 percent in carrying on this branch of the work. A summary of the game-fish laws for 1937–38, with special reference to black bass, was prepared and published, also several leaflets on subjects pertaining to angling.

Whaling.—The total number of licenses issued for taking whales was 15—covering 3 shore stations and 12 catcher or killer boats. The total revenue received for these licenses was \$4,750 which was covered

into the United States Treasury.

The Division prepared, in accordance with the terms of the Whaling Convention of September 24, 1931, two statistical reports covering the number of whales captured, species, size, etc., and has made biological studies of the samples of stomach contents taken from whales captured by United States vessels. It has completed two biological reports which, together with the two statistical reports, were forwarded to the International Bureau of Whaling Statistics, Sandefjord, Norway, as required under the convention.

Angling.—Requests for information on how, when, and where to fish with rod and line have increased during the fiscal year. Thirty-nine permits, required by act of Congress, to take certain small bait

fish in the District of Columbia were issued.

VESSELS

Fifteen vessels of the Alaska service cruised approximately 107,000 nautical miles in the fiscal year 1939, as compared with 117,000 miles in the previous year. The *Penguin* covered about 30,000 miles, the *Teal* 11,000 miles, and the *Crane* 9,000 miles. Owing to the accidental grounding of the *Brant* on Williams Reef on July 15, that vessel was out of commission during a considerable part of the season, and its total mileage in the fiscal year was only about 8,000 miles.

The Penguin made five round trips between Seattle and the Pribilof Islands, carrying personnel and emergency supplies. Interisland service also was performed, and native workmen from the Alaska Peninsula were transported to the Pribilofs to assist with sealing activities. Two trips were made to the western Aleutians in con-

nection with sea-otter investigations and patrol.

The Auklet, Kittiwake, Merganser, Murre, and Widgeon were engaged in fishery protective work in southeast Alaska. The Eider operated in the Kodiak area, the Ibis at Chignik, the Red Wing in the Alaska Peninsula area, and the Coot on the Yukon River. The Blue Wing was on Prince William Sound and also assisted in the patrol of southeast Alaska.

The *Teal* operated on Cook Inlet, carried on the stream survey in the Prince William Sound area, and assisted in the stream survey and general patrol in southeast Alaska. The *Crane* transported per-

sonnel and supplies between Seattle and Bristol Bay and patrolled the Alaska Peninsula area. The Scoter was used on Bristol Bay and relieved the Crane in the Alaska Peninsula area for about 10 days.

The Brant was used in general supervisory work, chiefly in southeast Alaska, although a trip was made westward as far as Anchorage. In December this vessel transported employees of the Bureau between Seattle and points in southeast Alaska for the conduct of hearings on the Alaska fishery regulations. The Brant was based at Juneau for approximately 3 months at the beginning of the year to render service in connection with the biennial session of the Territorial Legislature.

The Scoter engaged in the fur-seal patrol in the vicinity of Neah

Bay, Wash., in the spring of 1939.

The *Pelican* was engaged in exploratory trawling to determine the abundance and distribution of shrimp in the offshore waters of the Gulf of Mexico.

APPROPRIATIONS

Appropriations for the Bureau for the fiscal year aggregated \$2,220,200, as follows:

Salaries, Bureau of Fisheries	\$150,000
Propagation of food fishes	962,000
Construction of fish screens	20,000
Maintenance of vessels	173, 0 00
Inquiry respecting food fishes.	338, 000
Fishery industries	83, 600
Fishery market news service	70,000
Alaska fisheries service	270,000
Enforcement of Black Bass and Whaling Treaty Acts	17, 000
Mississippi Wild Life and Fish Refuge	17, 900
Fish cultural station	6, 500
	112, 200
Travel expense	,

\$2, 220, 200

APPENDIX I TO REPORT OF COMMISSIONER OF FISHERIES
FOR THE FISCAL YEAR 1939

UNITED STATES
GOVERNMENT PRINTING OFFICE
WASHINGTON: 1939

ADMINISTRATIVE REPORT SERIES

Since the advent of the Administrative Report Series, considerable confusion has arisen concerning its system of numbering the separates composing it. Inasmuch as the Reports of the Divisions vary in order from year to year, many have found their designations as "Appendix No. I, II, III, or IV" very confusing. To relieve this, it has been decided to number them as "Administrative Report No. -." Inasmuch as 20 separates had already been printed in this series before starting the numbers, it was deemed advisable to begin the numbering with Administrative Report No. 21. Of course, numbers cannot be printed on those already off the press, but for the information of those who wish to know what the first 20 were, they are numbered for filing purposes as follows:

No. 1. Report, Commissioner of Fisheries, 1931.

No. 2. Alaska Fishery and Fur-Seal Industries, 1930.

No. 3. Fishery Industries of the United States, 1930.

No. 4. Progress in Biological Inquiries, 1930.

No. 5. Propagation and Distribution of Food Fishes, 1931.

No. 6. Report, Commissioner of Fisheries, 1932.

No. 7. Alaska Fishery and Fur-Seal Industries, 1931.

No. 8. Fishery Industries of the United States, 1931.

No. 9. Progress in Biological Inquiries, 1931. No. 10. Propagation and Distribution of Food Fishes, 1932.

No. 11. Alaska Fishery and Fur-Seal Industries, 1932,

No. 12. Progress in Biological Inquiries, 1932.

No. 13. Fishery Industries of the United States, 1932.

No. 14. Propagation and Distribution of Food Fishes, 1933.

No. 15. Fishery Industries of the United States, 1933. No. 16. Alaska Fishery and Fur-Seal Industries, 1933.

No. 17. Progress in Biological Inquiries, 1933.

No. 18. Propagation and Distribution of Food Fishes, 1934.

No. 19. Alaska Fishery and Fur-Seal Industries, 1934.

No. 20. Fishery Industries of the United States, 1934.

Note that the last Commissioner's Report was for 1932. Since then its place has been taken by a reprint from the Report of the Secretary of Commerce under the title "Bureau of Fisheries." Inasmuch as it is no longer a Bureau publication, it is not numbered; but it will be supplied to any who request the Report of the Commissioner for any year since 1932.

Administrative Report No. 35, Appendix I to Report of the U. 8. Commissioner of Fisheries for 1939. Approved for publication June 1, 1939.

INTRODUCTION

The fundamental objectives and general characteristics of the research activities of the Division of Scientific Inquiry have been presented at considerable length in the previous annual reports of "Progress in Biological Inquiries" together with detailed reports of the individual research projects. The underlying philosophy of fishery conservation based on a continually growing body of scientific knowledge is now so well understood and the program of investigation under way during the past decade has justified itself so completely, both in its theoretical aspects and its practical applications, that it has acquired a momentum that in itself is a protection against irresponsible diversion of interest or activity into byways of local application or temporary value. A lengthy introduction to the major purposes of the various investigations reported in detail herein is therefore unnecessary.

Each of the recent years has seen the development of new projects of investigation that contribute to a well-rounded scientific program designed to afford still more complete answers to the original questions as to "what diminution in the fish supply of our coastal and inland waters has occurred, to what causes the same may be due, and what remedial measures may be adopted?" With the passing of the years new techniques of investigation have been developed or have been adapted from other fields of scientific endeavor. New concepts of the reactions of marine fish populations to commercial fishing have developed and new knowledge of the natural requirements of fish in inland waters and of means of their management for sustained yield

has accumulated.

Time has also permitted the ripening and the fruition of a series of fishery investigations, always time-consuming, so that during the year a number of definitive reports have been completed which, it is hoped, will be published in the near future. At the same time, and coincident with economic recovery, additional appropriations during the past few years have permitted the undertaking of new projects, bringing to hitherto neglected fisheries the benefit of research and the examination of their abuses or deficiencies and paving the way for

their ultimate rehabilitation and protection.

During 1938 a new project of considerable magnitude was undertaken by the Division—an investigation of the red-salmon fisheries of Bristol Bay, Alaska. One of the richest and most productive red-salmon fishing areas in the world, Bristol Bay, an arm of Bering Sea in western Alaska, receives endless replenishment from the spawning grounds of five major tributary river systems. The fishery there has developed over many years until it reached a reasonably stable maximum at the beginning of the past decade. Three years ago, however, the fishery was menaced by an exploration seeking to establish commercial fisheries on the high seas to intercept the run

of spawning fish en route to their native streams. The development of a commercial fishery in the offshore waters of Bristol Bay could only result in the disruption of the industry ashore, which takes its supply from coastal waters under strict regulation of the Federal Government, for adequate escapement of fish to the spawning grounds must be assured if the resource is to be maintained. The threat of developing an offshore fishery, therefore, was the occasion, if not the primary cause, of the undertaking of a comprehensive investigation of the Bristol Bay salmon, for the fundamental objective in such a study is to acquire sufficient knowledge of the natural history and the requirements of these fish and the factors that favor or hinder survival of each year's brood to permit a more certain and a more flexible control of the commercial fishery in the interest of wise management.

The investigation has been divided into two major phases—a study of the life of the salmon in fresh water, including the varying success of annual propagation and the factors that affect it and the natural requirements, habits, migrations, feeding conditions, and survival of

the salmon during their life in the sea.

With the aid of the United States Coast Guard cutter Redwing, a program of hydrographic investigations in the offshore waters of Bristol Bay was undertaken to study the oceanic conditions that so profoundly affect the well-being of the salmon schools. During 1939 this program will be expanded to include experimental fishing to study the schooling of fish, their routes and times of migration, their relative mortality, and the probable effects of the commercial fishery upon the supply. Likewise, a more intensive study of the stream life of the salmon will be undertaken to determine the success or failure of spawning and the responsible factors, in the hope of perfecting a system of prediction of future yields that will simplify the economic exploitation of the fishery and facilitate governmental regulation.

A special fund of \$20,000, provided by the appropriation act for the fiscal year ending June 30, 1939, permitted the establishment of another new project of considerable importance. This fund is for the construction, operation, and maintenance of fish screens and ladders on Federal irrigation projects and the conduct of necessary investigations and surveys, preparation of designs, and supervision of construction. It also, for the first time, permits the Bureau to discharge its obligation to determine the requirements for fishways or other fishprotective devices which, under the terms of the Federal Water Power Act of 1924, the Secretary of Commerce is authorized to prescribe at dams constructed under licenses issued by the Federal Power Commission.

With this authority a Hydraulics Section was established, under the supervision of the Division of Scientific Inquiry, employing a competent biologist for the study of fishway requirements and an experienced engineer for the design of the fish-protection facilities. During the latter part of the year the engineer who was first employed not only assisted in the design of fish screens constructed with emergency funds in the Pacific Northwest States, but also redesigned a screen in the Pishkun Reservoir, Montana, which had proved ineffective. Important consulting services on screens and ladders were

also afforded to other agencies.

This illustrates a recent trend toward the development of service activities as a part of the regular work of this Division. In recent years there has been a rapidly growing number of requests from the State fish and game commissions, fish and game clubs, and other organizations for technical services and advice in connection with stream surveys, stream improvement, pollution surveys, examination of the quality of water in hatcheries or rearing ponds, development of fishing lakes and reservoirs and the screening of their outlets, discovery of the causes of mortality of fish in lakes, ponds, and streams, the treatment of fish diseases in hatcheries, and the like in amazing variety.

It is clearly recognized that satisfying these demands is a valuable function which the Bureau of Fisheries should render to the tax-payers—services that, because of their technical character, can only be furnished by scientifically trained personnel. There is a serious question, however, to what extent the funds appropriated for investigation in a field which so urgently needs the development of fundamental scientific principles should be applied to routine activities which, while locally useful, contribute little to fishery science. Obviously a balance between original research and these practical services should be maintained, for the requests for service are so numerous that if an attempt is made to satisfy them all the major program of scientific investigation would be handicapped.

It is not suggested that the Hydraulics Section will not make important contributions to the conservation of the fish supply, particularly in the Northwest where extensive irrigation projects constitute a major hazard to migrating salmon and trout, nor that the studies in connection with the design of fishways or screens will not contribute also to an understanding of the habits and requirements of these fish. The Hydraulics Section, however, is primarily a service agency and hence is properly financed by a separate appropriation.

Normal development and improvements, including minor modifications or extensions of activities, have occurred in all of the other major research projects of the Division, the details of which will

appear in the following reports of progress.

COOPERATION

In previous reports the Bureau has been pleased to acknowledge a growing spirit of cooperation in fishery research among the various governmental departments, the States, and private organizations. This trend has been continued during the past year without abatement. Outstanding examples of cooperation in fishery conservation are afforded by the United States Forest Service, United States Bureau of Reclamation, the Coast Guard, and the Tennessee Valley Authority. Many States have likewise contributed either by actually furnishing funds, personnel, or other facilities, or through a less tangible but an equally real spirit of sympathy and support.

The most ambitious cooperative project undertaken by the Division of Scientific Inquiry during the year was a survey of the marine

fisheries of Long Island, N. Y., the major portion of which program was financed by the State Conservation Department and carried out largely by State personnel. Several of the New England States are making active plans to assist in the collection of vitally necessary fishery statistics applicable to the biological problems of maintenance of supply. Specific acknowledgement of cooperation and assistance of many other States and organizations is made in connection with the individual reports of projects.

NORTH AMERICAN COUNCIL ON FISHERY INVESTIGATIONS

Since 1921 the United States has participated, through membership in the North American Council on Fishery Investigations, with Canada, Newfoundland, and France in planning and coordinating studies of the fisheries of the North Atlantic area in which all four nations have a material interest. The twenty-fifth meeting of the Council was held in Boston, Mass., on Oct. 4-7, 1938, at the same time and place that the commercial fishery industries were holding their fishery exposition and convention. The Council invited the members of the Fishery Advisory Committee of the Department of Commerce, and other leaders of the industry, to attend a general session on Oct. 5 at which time fishery problems in the North Atlantic area were discussed and the program of fishery investigations carried on by Newfoundland, Canada, and the United States was presented.

The meetings of the Council are particularly useful in that they afford an opportunity for the investigators of the several fishery departments to discuss their technical problems and to exchange experiences and opinions regarding methods, objectives, and results. Nearly a score of fishery investigators in the various services were present and participated in sectional committee meetings dealing with groundfish investigations, shorefish studies, hydrographic research, and fishery statistics, affording the members of the Council a summary review of progress during the year in these fields and permitting them to modify their official programs accordingly.

COUNCIL OF STATE GOVERNMENTS

During the year important progress has been made toward the solution of vital problems of fish protection on the Great Lakes, where, under the present system of divided control, it is impossible to halt the depletion of the fisheries; and on the Atlantic scaboard, where the migratory nature of many of the important commercial species introduces difficult problems in fishery management and administration. This progress has resulted from the efforts of the Council of State Governments in cooperation with the Bureau of Fisheries and with fishery administrators of the various States concerned.

Two conferences on the problems of the Great Lakes fisheries were held during the year. The first of these, which met in Detroit on Feb. 25-26, was called by the Council of State Governments at the request of the Michigan Cooperation Commission. Action was taken by the Detroit conference as follows: (1) The Federal Government

was urged to discuss with Canadian authorities the establishment of an International Board of Inquiry to consider and recommend measures for the conservation of the Great Lakes fisheries. (2) A special Interstate Committee on Great Lakes Fisheries, consisting of representatives of the Lake States, with advisory members from the Bureau of Fisheries, the State Department, the Province of Ontario, and the Dominion of Canada, was appointed with instructions to offer its services to the State Department as an advisory body and to assist the States in their individual and cooperative efforts to conserve the fisheries. (3) A resolution was adopted urging the legislatures of the various States bordering on the Great Lakes to give their conservation departments discretionary power to promulgate rules and regulations regarding the taking of food fishes.

The Interstate Committee created at the Detroit conference met in Chicago on Dec. 5. This committee reaffirmed its endorsement of an international treaty, and also declared itself in favor of an interstate compact for the control of United States fisheries in the Great Lakes, pending the adoption of an international agreement. The committee again urged the granting of discretionary power to State fish and game commissioners as an aid to securing uniform regulations. Commissioners of Wisconsin, Indiana, and Minnesota now have such powers. It is expected that the legislatures of Illinois and Michigan may pass similar legislation in the near future.

Legislation authorizing the formation of an interstate compact among the Great Lakes States for the preservation of their fisheries

has now been passed by the Congress of the United States.

Plans for the conservation of migratory fishes of the Atlantic coast received marked impetus from action taken by the majority of the States from Maine to Florida at the Eastern States Conservation Conference held in New York on Nov. 19. A resolution was unanimously adopted petitioning the Congress of the United States to grant permission to the States to enter into a compact for the protection of migratory fishes in territorial waters. A committee was appointed to prepare a draft for submission to the States. This conference was called by the New York Joint Legislative Committee on Interstate Cooperation and all of the Atlantic Coast States, with the exception of New Hampshire, North Carolina, South Carolina, and Florida, sent one or more delegates. Another conference will be called at some future time to consider a specific draft of the interstate compact before efforts are made to secure its adoption and ratification.

PUBLICATIONS

As was intimated above, a number of important investigations, some of which have been under way for a period of 10 years, have come to completion during the year and reports are now ready for publication. There is considerable doubt, however, at the present time, regarding their probable date of release to the public, for funds available for printing have suffered a progressive decline since 1930. This shortage of funds applies to the publication of the results of investigations by the Bureau as a whole and necessarily restricts and limits the usefulness of the data acquired through many years of

work and at the expenditure of a considerable sum of money. In 1930 printing funds amounted to 14.2 percent of the amount expended on the various research projects by the Bureau of Fisheries but this percentage has declined until in 1938 only 4.7 percent of the amount of money available for investigation was available for the publication of the results of investigations. It is obvious that the accumulated findings of research, filed without publication, have little value.

Reflecting the meager amount of funds for publication, the follow-

ing brief list of papers issued during the year is presented.

DAVIDSON, FREDERICK A., and LEROY S. CHRISTEY.

MULTIGRAPHED PUBLICATIONS

UNITED STATES BUREAU OF FISHERIES. The Progressive Fish Culturist. Memorandum I-131, 8 issues.

Progress reports of the investigations conducted by the various sections, prepared in the main by the section heads, are given in the following pages:

NORTH ATLANTIC FISHERY INVESTIGATIONS

WILLIAM C. HERRINGTON, in charge

On the basis of landings at the three principal New England ports during the first 11 months of the year, the total catch of the New England vessel fisheries during 1938 will be approximately 4 percent greater than that during the previous year, but the value will be 9 percent less. The increase in catch is largely the result of considerable increases in the landings of redfish (rosefish), whiting, and mackerel, which more than offset declines in haddock and cod." decrease in value reflects the decline in price for nearly all species.

The past year also witnessed a general slowing down in the program of replacement of the old steam trawler fleet by modern vessels. During the year, but 3 new trawlers of the so-called super-trawler class were launched, compared with 10 during the previous year. The addition of new boats to the fleet has been partially or completely balanced by the decommissioning of older boats, so that the total intensity of the fishery did not change as much as the construction of new boats would indicate.

Probably the outstanding development in the New England fisheries during 1938 was the recovery of the mackerel fishery to more normal proportions after the disastrous year of 1937, and the start toward the development of a commercial tuna fishery in the Gulf of Maine. From the total of 14.000,000 pounds landed in 1937, the mackerel catch increased to 29,000,000 pounds in 1938; while the offshore tuna fishery showed an increase from around 110,000 pounds in

1937 to about 760,000 pounds in 1938.

The catch of both cod and haddock declined somewhat from that of the previous year, but it has not yet been possible to make a sufficiently complete study of the factors involved to determine whether this decline was due to a decreased fishing effort or to a decreased abundance of fish. Probably the most significant trend in the haddock fishery was toward the greater concentration of the fishery on scrod haddock, a trend which it is believed is definitely prejudicial to the future of the fishery.

Development of a Gulf of Maine shrimp fishery appears to be definitely under way. In the spring of 1938, between February and April, a total of about 75,000 pounds of shrimp was landed at Portland by small otter trawlers which caught them in inshore waters along the coast of Maine and New Hampshire. Smaller quantities

were landed at other ports.

In the New England offshore fishery, the principal problems continue to be the determination of the causes of the great fluctuations in yield and the development of methods which, if adopted by the industry, will reduce these fluctuations and maintain the yield at the highest practical level. Although good progress is being made on the species now under study (haddock, flounders, and mackerel), no biological work has been possible on the highly important fisheries for cod, redfish, pollock, and swordfish.

Pressing problems are developing in the inshore fisheries which support the small-boat fishing fleet and coastal population on long stretches of the North Atlantic coast. The most important problems here involve the improvement or maintenance of fisheries for flounders and lobsters, and the development of the fishery for shrimps.

Several important changes in the personnel of the North Atlantic staff were made during the year. J. R. Webster was assigned to continue the mackerel investigations, following the transfer of O. E. Sette to the West coast in October 1937, to assume charge of the Bureau's South Pacific Investigations. In January 1938, M. J. Lobell was transferred to this staff to carry on an investigation of the important flounder fishery; and in March 1938, Dr. G. A. Rounsefell also was transferred to carry on a comprehensive study of fluctuations in the abundance of North Atlantic groundfish, a problem which has demanded attention for some time.

The headquarters of the North Atlantic Fishery Investigations has remained in Cambridge and Boston, Mass. Harvard University has generously provided the staff with space and facilities in its biological laboratories. The cooperation of the Woods Hole Oceanographic Institution is gratefully acknowledged, as is the personal advice and interest of Prof. Henry B. Bigelow. The assistance and cooperation of fishermen and dealers in providing the use of their records, and in other ways, is also acknowledged with pleasure.

HADDOCK

The past year witnessed the continuation of several trends discussed in previous reports, but no noteworthy innovations or developments. Catch records for the first 11 months of 1938 (the only months yet available), show that the total amount of haddock landed at Boston, Gloucester, and Portland reached 138,000,000 pounds, a decrease of about 3 percent from the previous year; while the value was a little over \$3,000,000, a decrease of 15 percent from the previous year. This is the third successive year of decline in catch and the second successive year of decline in value since 1935.

The replacement of the old steam trawler fleet with new Diesel-powered boats continued during 1938, but at a slower pace than in 1936 and 1937. Two new trawlers launched late in 1937 began fishing in 1938, and three others were launched and placed in operation during the late fall and winter. However, these additions to the fleet do not necessarily mean a greater fishing intensity since they were probably more than counterbalanced by the decommissioning of old steam trawlers. The total number of trawler days at sea was somewhat less than in 1937, but the increased effectiveness of the new units probably compensated for much of the decline and it is likely that more detailed analysis will show that there was little change in absolute fishing intensity between 1937 and 1938.

The trend toward the increased utilization of species other than haddock continued, but at a much lowered tempo. These species, which in 1929 made up 34 percent of the landings of groundfish, in

1938 constituted about 64 percent. This change in the make-up of the catch is due primarily to the great increase in recent years in the landings of redfish (rosefish), whiting, cod, pollock, and grey sole. To a lesser extent it is due to the decline in the catch of haddock.

Another trend which was continued in 1938 was the increased concentration of fishing on scrod haddock, when these sizes were available. During the first 11 months of 1938, 45 percent of the haddock from Georges Bank were scrod, compared to 35, 38, and 36 percent during the 3 previous years and even lower percentages prior to that time. This appears to be definitely prejudicial to the future, inasmuch as haddock of this size still are growing rapidly and would be of considerably more value to the fishermen because of increased weight and increased value per pound, if allowed at least 1 more year's growth.

As a result of rather erratic exploitation and of natural factors which were neither understood nor even known, the catches of haddock have varied tremendously in different years, indicating a high degree of fluctuation in abundance or availability. Following 1927 the average catch per boat declined to an alarming extent (although the total catch was maintained until 1929-30 as the result of a great increase in fishing effort), and since then, has remained at a relatively low level. The fishery on the Nova Scotian banks has followed about

the same course and the effects have been much the same.

The principal problems of the haddock investigation, from its inception, have been to determine the extent and causes of these great fluctuations, and to determine what practical modifications in fishing methods or procedure could be adopted in order to partially or entirely eliminate the periods of low productivity. The final problem was to develop a plan for prosecuting the fishery which, if adopted by the industry, would permit the maximum continuous catch from the

area.

Analysis of extensive data collected during the course of the investigation has explained many of the factors controlling the condition of the fishery. During the period under most intensive study, the total catch increased from about 60,000,000 pounds in 1921 to nearly 250,000,000 in 1929, then dropped to about 140,000,000 in 1932 with some relatively limited increases and decreases since then. On the average, about 72 percent of this catch came from the Georges Bank In this region, the abundance of haddock, as shown by the average daily catch per trawler, had decreased rapidly from a relatively high level in 1921 to a low point in 1923, and had then risen precipitously to a peak in 1927. Since that year there has been a decline to an extremely low level in 1931, with little recovery since. The changes in this apparent level of abundance, particularly the low levels maintained since 1932, were due partly to the changing intensity of the fishery; but the relative success or failure of year-class survival appears to have been a very important factor. Years of good and poor survival appear to occur in cycles, the causes of which are only beginning to be understood.

Independence of the haddock population in the Georges area from that on the Nova Scotian banks has been apparent. During the first two or three years of life, the growth rate for Georges fish is much greater than for haddock from the banks to the east; while in later years, the advantage is reversed. In most of the years for which data are available, the size composition of the populations in the two areas

was entirely different.

The principal spawning ground in the Georges area is on the eastern part of Georges, although, in some years, there has been a considerable concentration of spawners in South Channel. The principal nursery ground for one-year haddock is on southeastern Georges, while the other fish move further to the north and west as they grow older. These sizes also carry on much more extensive seasonal migrations (within the limits of this area) than the yearlings and 2-year olds.

Progress in 1938.—The investigation has continued under the direction of W. C. Herrington assisted by H. M. Bearse and M. S. Moses with assistance from J. R. Webster and G. A. Rounsefell on the Atlantis trawling trip, and from the latter on a tagging trip to the

Maine coast.

Dependable figures for total catch and relative abundance, by years and areas, have been and continue to be of primary importance to this investigation. For the past several years, it has been evident that recent data on relative abundance obtained from analysis of the haddock catch alone might not be entirely comparable to earlier years, because of the increasing importance of other species in the catch of the otter-trawl fleet. Although about 1929 haddock made up 60 to 70 percent of the catch of this fleet, in 1936 it comprised only about 36 percent. To determine the extent to which this increase in the catch of other species would affect the unit of fishing effort as applied to haddock alone, a comprehensive analysis of the entire catch taken by the fleet was necessary. During 1938, such analysis of groundfish catches was undertaken by Dr. Rounsefell. Since this work did not get under way until well on in 1938, no data are yet available as to the relative level of haddock abundance in 1938, or changes that occurred from 1937 to 1938.

Field work during 1938 consisted principally of the regular observations on the Boston Fish Pier and a trawling trip on the Atlantis in April-May. Data collected on the Fish Pier by H. M. Bearse included more than 55,000 length measurements, 3.000 scale samples, and interviews showing fishing grounds, fishing effort, and division of catch for all groundfish trips. The Atlantis trawling trip was under the direction of J. R. Webster assisted by G. A. Rounsefell and H. M. Bearse. Records were obtained covering "catch-per-hour'strawling" for haddock and other species, and data were obtained concerning length, sex, and age for all haddock as well as for part of the

cod and other species.

Analysis of abundance.—Original records for the otter-trawl fishery from 1914-22 have now been acquired. These new data are of inestimable value, as they include information on the scrod catch not previously available. Primary analysis of the data for the entire period 1914-37 has been virtually finished. When completed, this will show the average catch per trawler per day of large haddock, scrod haddock, and total fish, for a series of years extending from the time when the commercial fishery was relatively small to the present extremely intensive fishery. Preliminary conclusions from these data indicate that cycles of relative scarcity and abundance have appeared in the haddock populations over the entire period, which is marked by three periods of scarcity and two of abundance. Periods of abundance apparently result from a series of years with a high survival of young, while periods of scarcity result from a series with a poor survival. The years since 1930 are an exception, for since then the level of abundance has remained relatively low in spite of the consistently good production and survival of young. This condition appears to be the result of the increased intensity of the fishery in recent years. Cycles of good and poor survival of young appear to be related to the abundance of adults on the nursery grounds, the most favorable level being approximately that which prevailed in 1922 to 1924, 1929, and 1936.

These developments indicate that we are now approaching the stage where it will be possible to explain the causes for the great cycles of abundance which have been observed in the haddock fishery. It appears that the cycles of abundant and poor year classes are related to the varying abundance of large fish on the banks. Poor production or survival of young may result either from an overabundance of adults on the nursery grounds or from too great a reduction in the spawning stock. If the completed analysis of the material substantiates these indications, it will provide information of tremendous value toward development of a consistently good yield.

Population composition.—A considerable amount of information concerning the abundance and distribution of haddock was obtained from the trawled material taken on the spring Atlantis trip. One-and two-year fish were abundant, but older fish were relatively scarce. The 1-year fish were distributed about as in previous years, but 2-year fish, which previously were found in great numbers on Central Georges, in 1938 were almost entirely absent from this region. They were found in large numbers only on southeastern Georges and in South Channel. The latter location was particularly unusual, as but

few fish of this age had been found there in previous years.

Tagging.—Early in this investigation a series of tagging experiments was carried out, using haddock held in tanks and live cars to determine the most satisfactory tag for this species. A variety of special tags were tested in addition to the disk type (plaice label) and strap tag used by other investigations. The experiments indicated that a button type was most successful with the disk type almost as good. This work was followed by field experiments in 1932-33, involving the tagging from otter trawlers of 440 haddock with button tags and 52 with belly tags, and from line trawlers of 296 with button and 117 with belly tags. No returns were received from any of these experiments except for one button tag from the linetrawl tagging. In view of the successful retention of tags in the live-car experiments, it appeared that the failure of the offshore work was the result of high mortality due to the gear and depth. Experiments next were tried from small line trawlers in shoal water along the Maine coast. In this attempt, 296 button and 117 belly tags were attached. There were 6.4 percent of the button and 6 percent of the belly tagged fish recaptured and reported.

Owing to limited personnel and funds, no further work could be done on this subject in spite of its importance until Dr. G. A. Rounsefell took charge of the work in 1938. In June of that year, 265 haddock were tagged with button tags, 266 with disk tags, and 100

with an internal anchor tag designed by Dr. Rounsefell. Tagging was done near Mt. Desert Island from a small line trawler. planned to continue the work next year on a sufficiently large scale to provide significant conclusions concerning the intermigration between the population of Maine shore haddock and that on the offshore banks.

Principal requirements of the investigation.—The most urgent matters now facing the investigation are the completion of the study of variations in haddock abundance and total catch, analysis of the age and size composition of the commercial catch to show the effect of year-class strength on the fishery, study of the differences in growth rate between different year classes and fishing grounds, and the determination of the extent of intermigration between the various grounds. The first is now well on the way toward completion, but, although considerable progress has been made on the others, the work has been greatly handicapped by the lack of vessel facilities for collecting basic data on the offshore fishing grounds. The generous cooperation of the Woods Hole Oceanographic Institute in providing the occasional use of the Atlantis at nominal cost to the Government has been of great help, but to no considerable degree has this served to displace the need for a vessel built and equipped for otter trawling and hydrographic duties and regularly assigned to fisheries work. Such a vessel is particularly needed for a systematic sampling of the young fish population at least twice a year to evaluate the distribution and abundance of each year class before it reaches commercial size; determine its mortality rate from natural causes and from the commercial fishery; and study the growth rate of the young fish.

A vessel is urgently needed to carry on further work on offshore tagging. Adequate experiments should provide data of great value concerning haddock migrations, growth rates, and mortality rates. Preliminary attempts to carry on the work from commercial vessels have proved to be a complete failure (except from small line trawlers along the Maine coast), presumably because of the high mortality of the fish resulting from the effects of the commercial gear. It does not appear that these difficulties can be overcome without the use of a research vessel to develop and use special methods for catching

and handling the fish.

MACKEREL

The 1938 mackerel season began late in March, and, because of growing emphasis on winter activity following the 1937 failure, was still in progress at the end of the year. Total vessel landings for the season will be approximately 29,000,000 pounds, about double the 1937 catch. Prices dropped back to the 1936 level, close to 21/2 cents a pound, at principal New England ports. In general, fishermen fared better than in 1937.

Throughout its history the mackerel catch has been characterized by extreme fluctuations in yield. The mackerel investigation was undertaken to study the causes of these fluctuations, with a view to devising means of predicting the relative abundance of mackerel in advance of the season.

To provide a basis for understanding changes in abundance, catch statistics have been assembled covering the fishery from its inception-about 1804. These figures reveal a period of high catch level,

lasting from about 1820 to 1885. During this time the landings averaged roughly 80 to 100 million pounds annually, but were subject to violent fluctuations. The year 1886 ushered in a period of poor catches, lasting until the present day. In no year during this period have landings exceeded 65,000,000 pounds, while the annual average has been nearer 40,000,000 pounds. This low level has persisted so long as to be considered normal. However, the yearly fluctuations during the latter period, though less in amount, were as great in degree as those within the former period.

Investigations of mackerel behavior and life history have demonstrated that these fish range from the Middle Atlantic States to Canada. They school mostly over the inner portions of the continental shelf, generally avoiding small enclosed bays and regions over deep water. Analysis revealed two contingents in the population; one ranging between the offing of Chesapeake Bay and the Gulf of Maine and the other between southern New England and the Gulf of St. Lawrence. Both contingents probably spend the winter in

offshore areas near the southern portions of their range.

Spawning occurs between April and August. Fish grow 7 to 10 inches the first season, and attain a length of 10 to 14 inches by the end of the second year. Thereafter, growth is slower. The maximum life is 12 to 15 years, length about 22 inches, and weight from

3½ to 4 pounds.

Fish from one or a few year classes usually make up a season's catch, and persist as definite groups for many years. Discovery of this fact led to the belief that the numerical strength of these dominant year classes determines the success of the commercial fishery. On the basis of year class recruitment and mortality the investigation succeeded in forecasting the approximate yield for several successive years. In 1937, however, the mackerel catch fell about 40 percent below the predicted decline, indicating that some unknown factors were at work.

Progress in 1938.—The current mackerel investigations, now under the direction of John R. Webster, have been devoted to completing and bringing up to date the lines of investigation initiated by O. E. Sette, and to determining the factors which caused the relative failure of the mackerel fishery in 1937.

The abundance analysis for 1937 was based on more than 1,500 catch records and 35,000 length measurements. As shown by catch per unit of effort, abundance fell off everywhere along the coast. Compared to 1936, this decline was not much more than 30 percent for the area west of Nantucket Shoals, but exceeded 50 percent in

the Gulf of Maine area.

Study of lightship temperature records revealed that the surface waters of the extreme western Gulf of Maine in 1937 ran from 2° F. to 7° F. higher than those of the previous 10-year average. The departure from this norm was greatest during that portion of the mackerel season when the fleet operated in these waters. Since the offshore fishery fell so far below expectations during this period, it is suspected that hydrographic conditions were a factor in the decline.

Composition of the whole mackerel population in 1937 apparently differed from that of previous years since 1925. Analysis of length-

frequencies furnished strong evidence that the 1923 year class was still present, and probably the 1928 class as well. Except for the 1932 class, year classes following 1929 were present in better than 5 percent strength each. None of these stood out as dominant, however, a real departure from conditions only a few years before.

Field work during 1938 was conducted principally by F. E. Firth. This included details at Cape May and New York City in April and May, and at the Boston Fish Pier for the remainder of the year. Information on fishing effort and catch locations was obtained for over 1,000 trips and about 50,000 mackerel were measured for population composition analysis. In addition, 700 scale samples were taken for age reading reference. Late in June, Mr. Webster tagged 500 mackerel at Provincetown. There were but 5 returns, all local, within 1 week.

Preliminary studies of the 1938 catch show that the 1936 year class made large contributions to the fishery, with the combined groups of 1934 and 1933 next in importance. Detailed analysis of these data

will be undertaken in 1939.

The present tendency of the seining fleet to extend both ends of the season may make necessary some changes in methods of determining abundance. For furthering studies of hydrographic conditions, it appears advisable also to obtain a more representative norm of coastal surface water temperatures. If temperature be a real factor affecting the availability of mackerel, some measure of its significance must be found. Although some advance in the solution of these problems can be made with our present facilities, expansion is necessary in order to solve others. Direct evidence is needed of the fate of certain year classes which decrease in availability faster than others. The cause may be heavier mortality or mass changes in habitat through migration. A large-scale tagging program is needed to determine this point. Further study is needed also for an understanding of the relationship between the mackerel catch by purse seiners and pound nets in the same locality. Catch statistics alone are insufficient, since it is necessary to learn when these two types of gear sample the same or different populations and why. The aid of part-time assistants at strategic points is needed to collect such information.

The mackerel problem now appears to involve more than a study of year-class recruitment and mortality. Events of the past 2 years have emphasized the need for particular knowledge of oceanic conditions affecting the mackerel fishery. In view of these facts, it is believed inadvisable to attempt forecasts of future abundance until

facilities for determining these conditions are provided.

FLOUNDER

In 1935, the last year for which complete figures have been compiled, the total North Atlantic catch of all species of flounders amounted to about 39,000,000 pounds, and was worth approximately \$1,500,000. Five species compose the bulk of the catch. They are: (1) Lemon sole (Pseudopleuronectes dignabilis Kendall); (2) grav sole or witch (*Glyptocephalus cynoglossus* Linnaeus); (3) winter flounder or blackback (*Pseudopleuronectes americanus* Walbaum); (4) dab (Hippoglossoides platessoides Fabricius); and (5) yellow-tail (Limanda ferruginea Storer.) In addition, the fluke (Paralichthys dentatus Linnaeus), the four-spotted flounder (Paralichthys oblongus Mitchill), and the smooth flounder (Liopsetta putnami Gill) are landed in some quantities. Because of variations in life history and habitat, each of these species represents a different

problem.

Studies of winter flounders previous to 1938 were confined largely to tagging experiments. In 1931, R. A. Nesbit tagged a number of flounders at Woods Hole and devised the present methods of flounder tagging. Returns indicated that the winter spawning population dispersed in various directions during the spring and summer, and that long migrations were undertaken by some individuals. In the following winters many of these tagged flounders were recaptured at the original tagging area. During 1937, a number of fish were tagged in Rhode Island and in Great South Bay, Long Island. The recoveries from these experiments indicated a high intensity of recreational fishing. As before, returns indicated a dispersion from the tagging point. Little migration from Rhode Island waters occurred, a few fish being recovered in the Nantucket region. Significant numbers of fish tagged in Great South Bay were recovered at considerable distances from the tagging area, some individuals being taken as far away as Nantucket Shoals.

In January 1938, Milton J. Lobell began an intensive study of

In January 1938, Milton J. Lobell began an intensive study of the flounder fisheries of the North Atlantic area. The most pressing problem facing this investigation is to determine whether a decline in abundance is in progress. If the decline is serious, the reasons for it must be found and methods developed for a more efficient utilization of the stock. Determination of the total catch and catch per unit of effort must be made to cover as long a period as possible in order to determine the condition of the stock and the fluctuations in the fishery. To find the reasons for fluctuations in abundance or availability, various biological factors must be studied. These include the racial composition of the stock, age and growth, migrations, and many other problems that affect the abundance and avail-

ability of the species.

Statistics.—The first available figures for the North Atlantic flounder fisheries are for the year 1887. During this year a total catch of about 2,500,000 pounds was recorded. The peak year for flounder landings occurred in 1928, when approximately 51,000,000 pounds were reported. The years 1929 and 1930 were also important, since landings of about 49,000,000 pounds were made in each of these years. Although the value of the fishery cannot be accurately determined for the earlier years, in more recent times a basis of estimation is furnished by the value of flounders landed at the three principal New England ports, Boston and Gloucester, Mass., and Portland, Maine. In 1928, a 10,500,000 pound catch landed at these ports was valued at \$511,296. Since the total reported catch in 1928 for the whole region was about 51,000,000 pounds, or approximately 5 times as much, it can be conservatively stated that the value of the fishery was well over \$2,000,000.

The catch by species was given for the first time in 1937 in the statistical reports of the Bureau for the three principal New England ports. Gray sole landings were almost 8,000,000 pounds;

vellowtail about 4,000,000; lemon sole, 2,500,000; dabs, 2,500,000; and winter flounders slightly over 1,000,000 pounds. These figures, however, are not indicative of the total amounts landed by the entire fishery, or even of the proportions of the catch contributed by each species in New England and New York. Contrary to the situation prevailing north of Cape Cod, the bulk of the flounder catch south of the Cape is composed of winter flounders. Annual canvass figures for this area showed a decided decline, the landings having dropped about 37 percent from 1930 to 1935. Fishermen and dealers report a definite decrease in the average size of the fish. During the past 5 years an enormous sports fishery for winter flounders has developed south and west of Cape Cod, and particularly in Long Island. In some places the catch equals or even exceeds that of the commercial gear. In view of the decline of commercial catches of the winter flounder and the rising importance of the sports fishery, the work of the flounder investigation has been concentrated on this species.

Detailed and accurate statistics of the catch of winter flounders are not available for past years, owing to the fact that all species landed were lumped together, with no record of seasonal occurrence or grounds fished. In 1938, however, the Market News Service, with offices in Gloucester, Portland, Boston, New Bedford, Provincetown, and New York City, was able to furnish more complete and detailed statistics than could be procured formerly. In addition, the State of New York, through its Long Island Survey, collected much needed and detailed information on its fisheries. The State of Maine will adopt a statistical system in the early part of 1939, and other New England coastal States are expected to undertake a like program. With cooperation from these States, it will be possible to

obtain more satisfactory data in the future.

Tagging.—In cooperation with the States of New York and Connecticut, about 2,000 flounders were tagged in Long Island Sound and in a number of localities on Long Island. Fish were tagged in Great South Bay, Great Peconic Bay, Gardiners Island Sound, Port Jefferson, and Huntington Harbor in New York waters. In Connecticut, tagging of the local stock was conducted in the Mystic River and of the breeding stock at the Noank Hatchery. As in previous experiments, the twin disk celluloid tag was used. These were fastened just posterior to the head and below the dorsal fin

of the fish by means of nickel pins.

These experiments yielded valuable information on the movements of flounders and the relative intensity of the commercial and sport fisheries. The peaks of returns occurred from April to May and from October to November, indicating either that the fish were more available at that time or that fishing was more intensive. In general, an offshore movement in the spring and an inshore movement in the fall occurred. Summering concentrations in the Block Island region were composed of individuals from Long Island, Connecticut, Rhode Island, and the south shore of Cape Cod. Recoveries from Nantucket Shoals suggest that the offshore banks may be partially populated with fish from inshore grounds. Although a general dispersion of fish was indicated, evidences of directional migrations also occur, since it was found that in a number of cases minimum speeds of over 4 miles a day were recorded. The recovery of a large num-

ber of tags by recreational fishermen indicated that this type of gear took almost as many fish as the commercial gear in the tagging areas. Since year-round recoveries were made near the tagging locality, while seasonal recoveries occurred from points relatively far removed, it may be concluded that racial types, or at least groups with differing summer habitats, exist.

Age and growth.—Scale samples from Long Island flounders collected by the Long Island Survey and from Narragansett Bay, supplied by the Narragansett Marine Laboratory, were prepared, read, and the results partially analyzed. Particular attention was paid to the Long Island collection, since these data will be of value in connection with the survey conducted by the State of New York.

It was found that length frequencies, except for the 0-group and to some extent for the I-group, were useless in determining ages of flounders because of the multi-moded character of the length frequencies of fish other than the 0-group. Examination of the scales proved to be more enlightening, although the reading of some scales was complicated by false checks, double checks, and regeneration marks. Comparison of age and length availed but little, since oftentimes fish with two definite checks might be larger than fish with three definite checks, even in the same sample. In addition, it was found that females were consistently larger than males of the same age. Samples from one area showed growth rate differences when compared to samples from other regions. This evidence definitely indicates that the population of flounders is composed of groups with varied growth rates and possibly different habits in other respects. In general, the size at each age is: End of first year, 4% inches; end of second year, 71/2 inches; end of third year, 97/8 inches; end of fourth year, 111/2 inches; end of fifth year, 13 inches; and end of sixth year, 1334 inches.

Races.—In addition to positive evidence of the existence of separate races from tagging recoveries and age and growth studies, examination of the characteristics of juvenile fish also indicates that differences exist. These differences are in the length-width ratio, degree of twist in the snout, angle of head profile, location of the eyes, and ratio of head length to total length. Preliminary findings suggest two types of flounders: A thin, narrow-bodied type with the snout sharply twisted, a low head profile and a large head: and a relatively thick, wide-bodied type with a straight snout, high head profile, and small head. It is thought that these two types represent the offshore and inshore races, since both groups are known to spawn

in the same general areas.

These general lines of investigation will be continued in the future, with emphasis on the collection of detailed and reliable catch statistics and on a thorough study of the life history.

ANALYSIS OF GROUNDFISH ABUNDANCE

Analysis of groundfish abundance was undertaken early in 1938, under the direction of Dr. George A. Rounsefell. For some time the need of this work has been increasingly apparent because of serious problems created by this rapidly expanding fishery.

New England landings of fish and shellfish from 1930-35 (excluding 1934 for which figures are not available) have averaged

611,000,000 pounds annually, of which 437,000,000 pounds consisted of the various species of groundfish. Fluctuations in the abundance of haddock, which comprised about 45 percent of the catch during the above period, have been determined as part of a biological study of the species, but no information has been available concerning the other species—cod, pollock, hake, cusk, wolffish, whiting, halibut, rosefish, and the various flounders. During recent years the industry has been developing markets for all species, bringing about a marked change from former years when boats sought only haddock, and took other species but incidentally. This means that the total catch of any one species is now partially dependent on the abundance and market value of the others.

Various other factors must be considered in an analysis of groundfish abundance. For example, in a fishery that draws upon several species, the relative abundance of any one species is not necessarily indicated by the average catch of that species per unit of fishing effort. The average catch must be qualified by such information as the depths and grounds fished and the quantities of other species caught, so that it is clear whether the fishing effort was directed toward the catching of the species in question, or whether the average cited is merely of catches made incidental to the pursuit of another species. For example, the vessels seeking rosefish trawl exclusively in the deeper waters, around 70 to 100 fathoms. Only an occasional rosefish is taken in shallow water, and these fish are not caught in commercial quantities at medium depths. Therefore, a low catch of rosefish per unit of effort in shallow-water zones would not indicate a low abundance of rosefish in general. As another example, although the gray sole is taken to some extent at lesser depths, the bulk comes from certain types of bottom in the deeper water. The lemon sole, on the other hand, is abundant only in shallower areas. These differences in habitat have raised several problems of analysis, the solution of which is treated more fully below.

Another major problem is the study of the changes in the fishing fleet in respect both to numbers and to size and type of vessel, in order to gain a measure of the total fishing effort expended. For a great many years nearly all of the groundfish were taken with hookand-line, but in the last 20 years there has grown up a huge and expanding otter-trawl fleet. At the same time, the number of line trawlers has gradually decreased until they are now a minor factor in the fishery. Changes in the vessels affect not only their efficiency in respect to their chosen type of gear but also their adaptability to other gears. Many vessels are so constructed that it is possible to shift to whatever gear is producing the greatest monetary reward at the moment. This adaptability means that there exists a great potential capacity to take any particular species. Although this capacity is seldom exercised to any great extent, owing to an economic balance. the ability to shift fishing effort from one species or fishing bank to another must be realized and fully considered before judging the effect upon any species of changes in the abundance of another.

The total catch during this period of expansion has remained at a high level, owing principally to two developments in addition to the increase in number and efficiency of the fishing vessels. One important factor in maintaining the poundage has been the shift to other species, such as the rosefish. From 1930-35, this species contributed

but 4,000,000 pounds a year, but in 1936-38 it averaged over 60,000,000 pounds. The rosefish is now sold throughout the Midwest and South as frozen fillets of "ocean perch." Another factor has been the increased dependence of the vessels on the banks off the Nova Scotian coast. Even if these banks can stand considerably more fishing, their distance from port means greatly increased cost of production. In the past few years there has been a great increase in the amount of trawling in deeper water, out to the 100-fathom curve and beyond, because of the demand for rosefish and gray sole. Since most of the available banks and most of the commercially abundant species are now being fished, it becomes increasingly clear that the future of this huge fishery depends upon utilizing the present banks and species to the best advantage.

The main problem then is to assess the three variables, total catch, fishing effort, and abundance, in order to determine for each species whether it can yield larger quantities or whether it has already reached the point where an increase in yield will give a larger pro-

duction only at the expense of the future.

For this task the investigation has access to the following records: The poundages landed by species by each vessel for each trip from 1918 to date at Portland, Gloucester, and Boston (except for Boston landings at T Wharf) are available. For the vessels of over 50 gross tons, the actual weighed-out weights are given, but for the smaller vessels (5 net to 50 gross tons) the Boston records and some of the other records are hailed weights (i. e., estimates of the catch made by the captain when the trip is put up for sale at auction.) Since 1928, each slip also shows the type of gear the vessel employed in making the catch.

The record of the total annual catch by species of each fishing vessel (i. e., boat over 5 net tons) in New England since 1928 has been made available through the cooperation of the Division of Fishery Industries. These records are obtained by canvassing the fishermen themselves once a year to determine their catch. These records also show the gear used by each vessel, and, when more than one type is used, it shows the amount of each species caught by each

type.

Since 1932, the haddock investigation has maintained a man at the Boston Fish Pier to interview the captain of each groundfish vessel, of over 50 gross tons, each time the vessel lands. These interviews give the day and hour of departure from and arrival at the pier, the locations fished by rectangles covering 10 minutes of latitude and 10 minutes of longitude, the depth fished, the proportion of the fishing time spent on each bank, and the proportion of the fish caught on each bank.

Analysis of abundance.—The methods used in analyzing these records for the haddock investigation are in general applicable to the groundfish analysis (which will in the future include the portion of the haddock investigation dealing with abundance), but had to undergo certain modifications on account of the tremendous mass of data to be handled and the differences in habits between the various species to be studied.

Through a project of the Works Progress Administration it was possible to obtain several needed assistants. The large accumulations

of catch-record receipts for the 21 years from 1918-1938 have all been sorted by month according to vessel and type of fishing gear, and

filed so as to be readily accessible.

Using these records of landings in conjunction with the information obtained at Boston from interviews with fishing vessel captains, the relative abundance is being calculated for each species for the 7-year period 1932-38 from records of selected groups of otter traw-The procedure followed by the haddock investigation of subtracting running time of the vessel to and from the fishing banks, as well as time lost by bad weather, etc., in order to calculate the time spent in fishing on each bank, has been retained.

In order, however, to take care of the differences in the depth habitat of the various species, the banks have been divided into three depth zones, namely: Shallow, 0-30 fathoms; medium, 31-60 fathoms; and deep, over 60 fathoms. The allocation of catches into depth zones has been simplified by using the 10 minute unit area rec-

tangles mentioned above.

The increased fishing for rosefish and gray sole in the deep zone within the past 3 years, the inauguration of depth zones, and the analysis of additional data concerning fishing grounds obtained since 1936, made it advisable to revise the statistical subarea boundaries in International Areas XXI and XXII. These were reoutlined on the basis of 39,632 days' fishing, in the various unit areas. Three subareas were eliminated from Area XXII by amalgamation and many minor adjustments were made in an attempt to simplify the analysis of the data by adjusting the boundary lines to the natural fishing concentrations. The handling of this large mass of data has been simplified by the use of cards which permits wide latitude in the grouping of areas or depths, and is invaluable in the assembling of the material for correlations.

The current analysis of these data, starting January 1, 1939, will be tabulated by the punch-card system that has been used for some years by the Bureau in the preparation of the monthly bulletin on the landings at Boston, Gloucester, and Portland by type of gear, species, and fishing bank. The punch card has been revised and the depth zone and calculated fishing time added to the information previously punched. Mr. Bearse interviews the vessel captains, and, by means of these interviews, supplies the Division of Fishery Industries' agent with these additional data. By this means it will be possible to obtain current data on abundance, which, despite its use-

fulness, is available for very few fisheries.

Total catch by areas.—A knowledge of the relative annual abundance does not permit any estimate of the productive capacity of a

stock of fish without information on the total catch.

The landings of fishing vessels of over 5 net tons at Portland, Gloucester, and Boston (except for Boston landings at T Wharf) are shown both by type of gear used and by the subareas (fishing banks) where caught, in the monthly bulletin of the Division of Fishery Industries. However, these comprise but 65 percent of the New England groundfish landings.

The only records of total catch available for New England have been those of the Bureau's annual canvass; but, besides not being taken in some years, they cannot achieve a high degree of accuracy because a large share of the individual fishermen from whom the estimates are obtained do not keep accurate records. In addition to this disadvantage, the annual canvass totals do not show either the season at which the catch was made, or the banks from which it was derived.

In cooperation with the Division of Fishery Industries and other members of the North Atlantic staff, an attempt has been made to encourage the New England States to install systems of collecting more complete and accurate statistics than those now available. One of the best systems for collecting such statistics is the use of triplicate receipt books by every fish buyer, so that a copy of each purchase showing the weighed-out poundage of every trip is available to the dealer, the fisherman, and the State. Such a system has been in use in California since 1915 and has been eminently successful.

The State of Maine inaugurated such a system on January 1, 1939, and the Bureau is aiding in getting it under way. Other New England States also are becoming more interested in obtaining better statistics of their fisheries, and the Bureau is encouraging and co-

operating in the installation of such systems.

The fact that a fair share of the New England groundfish catch not landed at the three principal ports is caught in the inshore areas (as opposed to the large quantities from the offshore banks landed at the three ports) is shown by a preliminary analysis of the annual canvass vessel schedules which has revealed a large fleet of small vessels operating largely in shallow, inshore waters, and fishing primarily for flounders. These small flounder vessels are most numerous south of Cape Cod, although some land at Boston and Gloucester and along the coast of Maine. The catches of these smaller, inshore vessels will be analyzed by the flounder investigation as they will necessarily have to be correlated with the life-history findings.

Composition of the fishing fleet.—The fishing vessels have undergone many changes in size, power, and type. As explained above, these changes in the number and type of the fishing vessels must be known if one is to judge either the relative difference in annual fishing effort or the potential fishing effort that can be unleashed in any particular direction whenever economic conditions warrant. Furthermore, without knowledge of the total fishing effort, it is not safe to assume that the relative catch from year to year of a particular amount of fishing effort is not influenced by differences in the amount of competition with other vessels fishing the same grounds.

Since 1928, the weigh-out schedules for vessels landing at the three principal New England ports have given the type of gear used in making each catch. These data (available for over 700 vessels) are being analyzed to show the number of vessels of each size and type of gear that fished during each month over this period of 11 years. A preliminary tabulation of a few of the years during which New England annual canvass data are available, showed over 260 additional vessels that landed only at minor New England ports. These latter vesels were chiefly small inshore flounder trawlers and gill-net boats, although a few fair-sized vessels are included from Provincetown and New Bedford.

MIDDLE AND SOUTH ATLANTIC FISHERY INVESTIGATIONS

R. A. NESBIT, in charge

In Progress in Biological Inquiries for 1937 it was pointed out that the fisheries of the Middle and South Atlantic States offer an opportunity to benefit from scientifically controlled management. Increases in the amount of gear operated have diminished profits by increasing the cost of fishing and decreasing the yield. The problem of correcting excessive fishing and waste of small fish cannot be solved by individual fishermen. The responsibility rests on conservation officials, State and Federal, to advise fishermen what corrective measures

they must support in their own interest.

The reduced abundance which has resulted from overfishing has also caused widespread dissatisfaction among anglers. Many of them, made impatient by the long delay in devising and adopting sound conservation measures, are advocating drastic curtailment and even elimination of commercial fishing for certain species. Legislation to this effect has been introduced in several State legislatures. Other anglers recognize that most marine species are capable, under sound management, of supporting a prosperous commercial fishery without detriment to angling interests, and are supporting the Bureau and State conservation organizations in their efforts to serve the common interests of commercial producers, anglers, and the consuming public.

The problem is twofold; to determine what measures are needed and practicable, and to provide for a unified or coordinated means of putting them into effect. The Council of State Governments is sponsoring a proposal to provide for the necessary cooperation in research and administration through an interstate advisory body created under the provisions of an interstate compact. Preliminary meetings were held during the year and a committee is preparing a draft of a compact for consideration by the several States and by Congress.

As in 1937, the courtesy of the University of Maryland in furnishing laboratory facilities at College Park, and of the Charleston Museum for similar accommodations in Charleston, S. C., is gratefully

acknowledged.

SHORE FISHES

During 1938 the study of the shore fishes of the Middle Atlantic States was continued by William C. Neville. These investigations consisted principally of observations on the winter trawl fishery off the Virginia Capes, and cooperation with New York State in a biological survey of the marine fishes of Long Island.

Long Island Survey.—The Bureau participated in the Long Island Survey at the request of the New York State Conservation Department, acting principally in an advisory capacity. Mr. Neville, who was assigned as the Bureau's representative, spent most of the period from January to December on Long Island assisting the New York State biologists in the supervision and conduct of this work. Mr. Nesbit also served in an advisory capacity and Milton J. Lobell gave active support in certain phases of the study of the winter flounder. Mr. Neville assisted in the preparation and editing of a report on results of the survey, Mr. Nesbit preparing the section on squeteague and Mr. Lobell that on the winter flounder. The Bureau assigned the *Phalarope II*, with Joseph Armstrong as engineer, from the Woods Hole, Mass., station to Long Island from May 1 to July 1. This boat was used in a survey of the young fish populations of the bays and inshore coastal waters of that region. Some scientific equipment and

miscellaneous supplies were also furnished by the Bureau.

The main objectives of the Long Island survey were: (1) To provide information that could be used as a reliable basis for improving or maintaining good fishing insofar as the factors affecting the supply are controllable, and, (2) to determine by a census of fishing activities the recreational and commercial value of the marine district of Long Island to the citizens of New York State. Particular attention was given the winter flounder and squeteague because of the primary importance of these species to anglers and commercial fishermen. Other popular species as the fluke, striped bass, porgies, sea bass, tuna, and swordfish were given such study as 1 year's observations would permit. Fortunately, the information given by the 1938 survey is supplemented by results of similar study made by the Bureau during the past 10 years. Consequently, for some species, more definite conclusions could be drawn than otherwise would have been possible. Definite recommendations for the conservation of several species and for additional study of other species have been included in the report to be published by the New York Conservation Department.

Scup.—This species appears to be successfully withstanding the year-around activity of fishing which has resulted from the rise of the winter trawl fishery beginning about 1930, supplementing the summer fishery which has been operating on a large scale throughout the Middle Atlantic States since about 1900. Major fluctuations in the catch of scup have resulted more from variations in the success of reproduction than from fishing activities. A major increase in abundance occurred throughout the Middle Atlantic States beginning in 1929 and has continued in most of the subsequent years to date. This increase has been due largely to a series of successful spawning seasons beginning in 1927. Some waste of the supply is occurring because of prevailing fishing practices which permit the destruction of undersized and unmarketable sizes of fish. Correction of this abuse is difficult because the species is caught simultaneously with a variety of other fishes and by several different types of gear. Saving of scup by appropriate modifications of gear to insure the release of a large percentage of the small fish in good condition would probably involve a loss by gilling or escapement of marketable sizes of other kinds of fish of equal or greater value.

Progress on the report dealing with the causes of fluctuations in abundance of this species during the past years along the Middle Atlantic coast has been temporarily interrupted by Mr. Neville's assignment to the Long Island Survey. It is expected that this report

will be completed during 1939.

Winter trawl fishery.—The year 1938 marked the seventh anniversary of the commencement of the winter trawl fishery off the Virginia Capes. Beginning about 1931, the fishery has expanded rapidly. The total catch of the principal fishes—namely, sea bass, fluke, porgies, and croakers—has risen from approximately 4,500,000 pounds in 1931 to over 19,000,000 pounds in the past few winters. The fleet has

mcreased from approximately 30 vessels in 1931 to over 125 vessels in 1938 and includes, in addition to local vessels, boats from New Jersey, New York, and Massachusetts. Landings are made mostly in Virginia and, to a lesser extent, in New Jersey and New York City.

The economic importance of this winter trawl fishery has increased since its beginning in 1931 through the creation of new market outlets for its production, particularly in the Southern States. This activity has also affected the distribution of numerous fishery products and introduced keen market competition with other distributing and production points, particularly in the Middle Atlantic States.

The activity of the winter trawl fishery is of biological significance in the probable effect it may have on the supply of those species that comprise its catch. To date there is no evidence that the winter fishery has caused any significant decline in the supply of scup. A reasonable doubt, however, exists as to whether the sea bass and fluke can withstand successfully the combined withdrawal of the winter and summer fisheries. Continued decreases in the catch per unit of effort for both species in most of the recent years and a similar reported decline in the summer fishery indicates a diminishing supply, probably from actual decreases in abundance. It is recognized that the winter trawl fishery may not be wholly responsible for this diminution in the catch but that the activity of the sport and commercial summer fisheries may also be contributing to the reported decline. A detailed study of fluke and sea bass, based on observations of the summer and winter fisheries, is therefore recommended to determine the cause of this decline and what corrections for restoring higher levels of abundance are necessary.

ANADROMOUS FISHES

Striped bass.—In 1938 two important reports dealing with the life history and conservation needs of this species were submitted for publication. Dr. Vadim D. Vladykov submitted to the Maryland Conservation Department a report on his investigation in Chesapeake Bay in 1936 and 1937, and Dr. Daniel Merriman submitted to the Bureau his report on studies begun in 1936 under the auspices of the Connecticut Board of Fisheries and Game, and continued in 1937 and 1938 with the cooperation of the Bureau and several Atlantic Coast States.

The following are the principal results of these studies: The striped bass is subject to year-class dominance. When successful spawning occurs, as it did in 1934 in Chesapeake Bay, not only are local stocks greatly augmented, but, as a result of migration, abundance is greatly increased along the coast from New Jersey to southern New England, and even in the Gulf of Maine. Since the large brood of 1934 was produced in a year when spawning adults were scarce, it is doubtful whether increased numbers of spawners should be the primary object of conservation measures. Catch records and studies of age composition of the catch indicate that the numbers of such successful broods diminish rapidly. For example, the 1934 year class yielded only about one-fourth as many fish in 1937 as in 1936. Tagging experiments indicated that the fishery accounts for most of the decline. Protection of striped bass until they reach a length of at least 16

inches, measured to the fork of the tail (approximately 17½ inches over all), would lead to greater yields and larger profits from each brood, whether large or small. The number of fish reaching spawning size would also be increased.

Shad.—In marked contrast to the striped bass, the principal problem in shad conservation is maintenance of an adequate spawning reserve. Although pollution and obstruction of rivers have doubtless contributed to failure of reproduction, the decline in yield of more than 80 percent during the present century has not been limited to polluted or obstructed streams. On the contrary, some almost unpolluted rivers, such as the Edisto River in South Carolina, have been severely depleted and a fine recovery has been observed in the polluted Hudson River. This recovery is attributed to regulations limiting fishing to 4 nights a week and closing spawning areas to fishing.

In order to extend to other localities the benefits of the experience in the Hudson it is necessary to know the approximate spawning escapement there and to devise means of matching it substantially elsewhere.

Studies in 1938 indicate that the fishery removed somewhat more than 50 percent of the run. Of 196 shad tagged in Sandy Hook Bay in April, 53 percent were taken during the season in the river. Since tagging experiments usually underestimate fishing intensity it is probable that the fishery removed somewhat more than the indicated

percentage.

As a check on the estimate of fishing mortality by tagging experiments, scales were examined for spawning marks in 1938 to estimate the percentage of that year's catch contributed by fish which had escaped the fishery in 1937. On the basis of the reported catch in 1937, and assuming a fishing mortality of 60 percent, approximately 1,667,000 fish should have entered the river in 1937. Of these, about 1,000,000 were caught and 667,000 escaped. Assuming 10 percent mortality among these after they left the river, about 600,000 would be expected to return in 1938. From preliminary estimates of the catch in 1938 it appears that the total run to the river was about 1,250,000 fish. Of these about 600,000, or 48 percent, would be "repeaters" or fish which had escaped the fishery and which had spawned in 1937. Forty-six percent of the scales collected in 1938 bore spawning marks indicating that they had spawned in 1937, certainly in very good agreement with the expectation from the above estimate.

Similar collections of scales have been made in other rivers where depletion is greater. As might be expected, the percentage of scales having spawning marks is much lower, but, until records of the catch for 1937 and 1938 are available, the percentage escapement in 1937

cannot be estimated.

Because of the importance of reproduction in shad conservation a careful ecological study of the early life history is being made by John C. Pearson and Louella Cable. In 1938 intensive work was done in the Edisto River in South Carolina and it is expected that these studies will be extended to other rivers in 1939. In these studies especial attention is being paid to estimating rates of mortality at various stages in the early life history, at various levels of abundance of young, and under various conditions of temperature and volume

of river flow. For example, in 1938 most of the eggs taken in the plankton were dead. This may merely represent oversampling of the surface levels, for all plankton collections were made by surface nets. Further observations will be made in 1939 using bottom nets.

Such observations are expected to be of great value in estimating the optimum spawning escapement and also as a basis for estimating the most suitable size for releasing young shad produced in hatcheries.

Mr. Pearson conducted experiments in rearing shad fry in bass ponds at the Edenton, N. C., and the Orangeburg, S. C., Hatcheries. At the former station 6,500 young shad grew to a mean length of 35 mm. (13% inches) in 35 days in April and early May. The pond was drained and an attempt made to rear a second lot in the same pond. Only 500 fish survived. It is not known whether this was the result of diminished food production during the summer or to the activities

of predators accidentally introduced.

As a working hypothesis for the shad investigation, it has been assumed that the majority of the shad return to the river in which they were spawned. The correctness of this assumption is being tested from several angles. The tagging experiments which were intended primarily to measure fishing intensity will also indicate whether adult shad seek the same river each time they spawn. (Five shad have been recaptured, after a lapse of a year, in the same river or in estuaries en route.) Vertebral counts of adult shad are being compared with those of juveniles taken in connection with the early life history studies. The scales of adult shad from each of several rivers are being compared with those of young shad. Marked differences have been noted in the size and appearance of the streamgrowth portion of the scales from different rivers, but until data from other years are available it cannot be determined whether these differences are characteristic of each year's brood in the individual streams. Attempts to tag juveniles have been unsuccessful thus far. but further experiments are planned.

SHRIMP INVESTIGATIONS

MILTON J. LINDNER, in charge

With an annual catch averaging well over 100,000,000 pounds, the shrimp fishery is the most important marine food resource of the South Atlantic and Gulf States. The Shrimp Investigations are designed to provide a thorough knowledge of the life history, migrations, ecological relationships, and abundance of this first-ranking marine organism of the Southern States as a basis for its intelligent conservation.

All the members of the scientific staff which, in addition to Mr. Lindner, includes William W. Anderson and C. Howard Baltzo, have been associated at different times during the year with each of the various field investigations undertaken. In addition to the Bureau employees, Albert Collier, Marine Biologist of the Texas Game, Fish, and Oyster Commission, has been actively engaged in conducting a cooperative research program in Texas under the general direction of Mr. Lindner. The Louisiana Department of Conservation has continued to furnish office and laboratory space in New Orleans for the headquarters of the investigation. In October,

Commissioner Rankin, of the Louisiana Department of Conservation, kindly arranged to supply more spacious quarters for the staff and collections at 336 Chartres St., New Orleans, La. The city of Gulfport, Miss., has continued to furnish dockage space for the *Pelican* and a storage room for equipment. Arrangements have been made with Dr. A. E. Parr, of Yale University, for analyses of the water samples, and with Dr. Dana Russell, of Louisiana State University, for analyses of the bottom core and mud samples taken during the cruises of the *Pelican*.

In the course of the shrimp investigations, which have been under way since 1931, it has been found that the common shrimp spawns during the spring and summer in the open waters of the Atlantic Ocean and the Gulf of Mexico. The eggs are not carried by the female but are extruded directly into the water. The young enter the inland waters at an early stage in their development. The extensive inland water areas of the South are the nursery grounds of the shrimp, where the young feed and grow. Those young not successful in reaching the nursery grounds perish. As the immature shrimp increase in size they gradually leave the nursery grounds and return to the ocean. The growth rate of the shrimp is quite rapid, and by mid-June or July, depending upon the locality, the young are of sufficient size to appear in the commercial fishery. By September, practically the entire catch is composed of these immature shrimp, for the adults disappear from the fishery as spawning progresses. Sexual maturity is attained in 1 year. The movements and behavior of the shrimp are affected by temperature, salinity, and tides.

Tagging experiments have demonstrated that shrimp are migratory. During the fall and winter the larger shrimp move south along the Atlantic coast from North Carolina, South Carolina, and Georgia into the waters off the coast of central Florida. In several instances tagged individuals have been picked up more than 300 miles from the place of release. The smaller shrimp, however, tend to remain in local waters and are not subject to such extensive movements.

In the Gulf of Mexico it was suspected that the larger shrimp, from the Louisiana coast at least, move off into deeper waters during the winter. With a suitable vessel and the proper equipment it was considered highly probable that a new winter fishery could be developed off the Louisiana coast. The *Pelican* was transferred to the Shrimp Investigations in 1937 for this purpose, but, owing to lack of funds, operation of the boat was deferred until January 1938.

The major program of work undertaken during the year falls into three general categories, namely: Offshore scouting operations with the *Pelican* in the Gulf of Mexico, tagging experiments along the Atlantic coast and the Louisiana coast, and ecological studies in Texas.

OFFSHORE OPERATIONS

Among the results of the 1938 investigations, the event of outstanding importance to the commercial fishery was the discovery of a winter concentration area for large shrimp off the central Louisiana coast. The *Pelican* began operations in January and operated continuously until June, when the loss of the trawling cable necessitated

a lay-up of 1 month for replacement. The boat was again placed in operation in July, but was laid up for engine repairs and for the duration of the dangerous hurricane season from August through October. Operations were resumed for a short period in November.

The offshore area from Mobile, Ala., 60 miles north of Brownsville, Tex., was covered with the *Pelican*. In this region 402 trawl hauls were taken and 96 hydrographic stations were occupied. From each haul observations were made on the quantity, sex, length, and gonad development of the shrimp. At the hydrographic stations temperature and salinity observations were secured for various depths, and core-tube and Petersen grab samples were obtained for study of the types of bottom and organisms present. Trawling was done in depths up to 180 fathoms. It developed during the course of the work that a small 9-foot trawl, towed at full speed, was admirably suited for scouting. As much as 8 gallons of shrimp have been taken with this gear in a half-hour haul.

That a winter concentration point for the larger common shrimp occurs off the Louisiana coast, in the region between Ship Shoal Buoy and Trinity Shoal Buoy, is quite evident from the data collected with the *Pelican*. As a result of the discovery of this area by the Bureau, boats operating from Morgan City, La., initiated a commercial fishery based on this offshore group of shrimp. A number of the Florida shrimp boats, which are better suited for offshore operations than the smaller and less seaworthy Louisiana craft, have migrated to Morgan City and Berwick, La., and have developed this

fishery to one of considerable magnitude.

No shrimp concentrations of any significant size were found between the Alabama coast and the mouth of the Mississippi River. Off Texas during April the common shrimp appeared to be scattered about the 10-fathom contour, but with no evident heavy aggregations. The less-abundant grooved shrimp was found in depths up to 70 fathoms but no commercial concentrations were encountered.

Inasmuch as a considerable amount of offshore work remains to be done in the Gulf, it is planned to continue these operations during 1939. The region between Mobile, Ala., and St. Marks, Fla., should be covered to determine the depth distribution of shrimp in this area and whether or not commercial concentrations occur. The Texas coast should be scouted as far south as the Mexican border during midwinter. The fishing grounds between Ship and Trinity Shoals should be covered at regular intervals during the spring, summer, and early fall to determine: (1) The extent and duration of the apparent onshore movement of the common shrimp during spring and early summer; (2) the fate of the adult spawning shrimp as the season progresses; (3) the magnitude of and the period covered by spawning; and (4) the time that the young shrimp begin to appear in this area after leaving the bays.

TAGGING EXPERIMENTS

For several years tagging experiments designed to provide information on migrations, growth rate, fishing intensity, and fate of the adult shrimp have been in progress throughout the South Atlantic shrimp fishing areas. Understanding of the fishery in this section depends largely upon the solution of these problems.

Previous tagging had established the fact that the larger shrimp move south along the coast during winter, concentrating in the waters between St. Augustine and Cape Canaveral, Fla. Indications of a return northward movement had been obtained from length-frequency distributions and prior tagging. Conclusive evidence, however, of this return movement had not been secured.

During 1938, 3,160 tagged shrimp were released from Cape Canaveral to St. Augustine in January, February, and March, a period representing the height and decline of the Florida winter fishery. From releases at Cape Canaveral returns were secured as far north as Fripp Island, S. C., a distance of some 250 miles. It is therefore evident that a return movement does occur. Whether this return movement is made at random or represents the return of shrimp to the region where they originated has not yet been determined.

Although the larger shrimp migrate to the southward during the winter, the small individuals remain in the local waters of Georgia. In January, February, and early March, 1,325 shrimp from this group were tagged and released in the area around Brunswick, Ga., in an effort to determine whether they also are migratory. The returns indicate that this class does not undertake any extensive movements. Additional tagging experiments in various areas along the entire coast would add materially to our knowledge of this group of so-called "local shrimp."

From April through August 3,200 tagged shrimp were released in the vicinity of Brunswick. The returns from these releases indicate that no extensive coastwise migrations were occurring at this season.

Because of the extensive and continuous migrations and movements of the shrimp, growth determinations by length-frequency distributions cannot be relied upon to present a true picture of the rate of growth over any considerable period of time. Neither can study of growth of confined individuals represent the true growth rate, owning to the extreme difficulty or impossibility of duplicating the widely varied changes in habitat that the shrimp undergo as they increase in size. Tagging experiments, therefore, provide the best source of information on the growth of the shrimp in its natural environment, as each shrimp is measured at release and upon recapture. Although many data have been accumulated, more tagging is required to arrive at an accurate approximation of the growth rate of shrimp during the different seasons of the year, and in different localities.

The determination of fishing intensity has long been a difficult problem. Although the percentage of returns from tagging experiments gives some indication of fishing intensity, detailed and accurate catch statistics are also necessary. None of the States in the area covered by the shrimp fishery has gathered catch statistics in a form suitable for analysis of the shrimp population density, a situation which is particularly deplorable in view of the magnitude of the fishery. Because of the lack of funds, personnel, and regulatory authority, it has been impossible for the shrimp staff to secure the necessary statistics. A serious effort was made during the year to secure voluntary cooperation of the fishermen in keeping daily catch records. Log books were provided to all boat captains willing to

maintain them. Results indicate that a venture of this nature can be successful only through frequent personal contacts with the men keeping the logs. One shrimp cannery in Georgia kindly allowed the transcription of its entire boat catch records from 1921 to 1937. These records, which were copied in 1938, should be of considerable value in tracing the progress of the central Georgia shrimp fishery during its period of most rapid development.

It is quite evident from the work done so far that if adult shrimp survive for 2 or more years in any quantities along the Atlantic coast, they must move into deeper offshore areas beyond the range of the present commercial fishery. This important information which is lacking in our knowledge of the life-history of the common shrimp can only be determined by thorough scouting of the offshore waters between Cape Hatteras and Cape Canaveral. Exact knowledge, which is not now available, of the depth distribution of the shrimp along the Atlantic coast during the spawning season is of particular importance in attempting to delimit the spawning areas. Tentative plans are being made for the use of the Pelican on the Atlantic coast

after the completion of the Gulf survey.

The expansion of the offshore fishery in the Gulf has raised the important question of whether these shrimp are of local origin or whether they are migrants from other States. It was deemed advisable, because of the urgent need for knowledge of the movements of shrimp in the Gulf, to suspend activities at the Brunswick (Ga.) station in the fall and transfer Launch 58 to New Orleans for tagging operations. The first of the Louisiana tagging experiments was inaugurated during December, when 2,300 shrimp were released between the Mississippi River and Ship Shoal. The objective of these experiments, which should be extended to cover the entire fishery, is to determine the migrations, growth, age, and fishing intensity of the Gulf shrimp. Tagging will be continued during the coming year as funds permit.

ECOLOGICAL STUDIES

The Texas Investigation is operated on a cooperative basis with the Coastal Division of the Texas Game, Fish and Oyster Commis-With the transfer of Kenneth H. Mosher to the Pacific Pilchard Investigations, the sampling of the commercial catch at Aransas Pass was discontinued. Albert Collier, of the Texas Commission, has conducted studies during the year to determine the relationship between the environmental changes and the distribution of shrimp in Aransas Bay. What effects do temperature, salinity, tides, currents, and food have on the reactions of the shrimp in its natural habitat? What determines the time when young shrimp leave the shoaler nursery grounds for Aransas Bay and later for the Gulf? Why does the success of the commercial catch fluctuate so greatly from day to day? Can these fluctuations be determined in advance? Is there actually a definite distribution pattern of shrimp in Aransas Bay, as appears to be the case from the commercial catch, and if such a distribution is present what is the cause? These and many other problems require solution for a better understanding and wiser utilization of the shrimp supply.

Stations were established at various points in Aransas and Copano Bays. These stations were occupied at regular weekly intervals when the weather and availability of boats permitted. At each station trawl hauls were made for shrimp, and temperature and salinity observations were taken. In the fall Mr. Collier instituted a weekly survey of the shrimp distribution in Aransas Bay. Hauls of 5 minutes duration were made with a small trawl in closely spaced parallel lines across the bay. From this work it appears that the shrimp follow a rather well-defined path across Aransas Bay in their movements from the more interior nursery grounds to the Gulf. During the coming year efforts will be directed toward determining the fundamental reasons for this distribution.

NORTH PACIFIC AND ALASKA FISHERY INVESTIGATIONS

Dr. F. A. DAVIDSON, in charge

The North Pacific and Alaska Fishery Investigations, with headquarters in the Fisheries Biological Station at Seattle, Wash., are concerned chiefly with the maintenance and rehabilitation of the salmon and herring fisheries of Alaska and the salmon fisheries of Puget Sound and the Columbia River. All of the major investigations in progress in 1937 were continued in 1938 with the exception of the Puget Sound sockeye investigation, which was discontinued in March 1938. An investigation of the Bristol Bay fisheries was undertaken in July 1938.

COLUMBIA RIVER SALMON FISHERIES

Investigations of the Columbia River salmon fisheries were continued during 1938 by J. A. Craig, A. J. Suomela, M. J. Hanavan, Z. E. Parkhurst, J. L. Wilding, W. M. Morton, and J. A. Coleman. Stream surveys.—One of the factors contributing to the depletion of salmon runs in the Columbia River watershed is the fact that important spawning grounds have been rendered inaccessible or made unsuitable for migratory fishes by the construction of irrigation diversions and by other activities of man. With the primary purpose of classifying those areas which may be rehabilitated, and of discovering means of making them accessible to fishes, an extensive stream-survey program has been undertaken and is now well under way.

During the early part of the season these stream-survey activities were centered in the Willamette River system. In this area surveys were completed on the McKenzie River, the middle and coast forks of the Willamette and Long Tom Rivers, and the upper portions of the North and South Forks of the Santiam. The Clackamas River survey was partially completed. The McKenzie, Middle Willamette, and the Santiam Rivers are the most important spring chinook

streams of the Willamette system.

The Payette River system in Idaho was surveyed during the month of August. In early years this river was one of the important salmon streams in Idaho. Chinook and blueback salmon and steelhead trout migrated to the headwaters of this river in large numbers.

Payette Lake, at the headwaters of the North Fork, is reported to have supported a run of blueback salmon. Dams without adequate fish protection are responsible to a great extent for the extinction of the salmon runs in this river. A dam constructed at Horseshoe Bend 30 years ago probably destroyed the blueback run which had entered Payette Lake, and limited the migration of chinooks and steelheads to the part of the river below this obstruction. In 1925 the Black Canyon Dam was constructed by the United States Reclamation Service. This dam is a complete barrier to all migratory fish, since no fish protection was provided. It is reported that there have been fewer salmon observed below the dam each year. The stream survey revealed that the amount of favorable spawning area in the Payette River system is great enough to provide facilities for a large run of fish, if access to the spawning grounds were provided.

Stream surveys were carried on in 258 miles of the Clearwater River, including the main river from the mouth to Kamiah Creek, Potlatch Creek, North Fork to Kelly Creek, Middle Fork, Sellway River to Meadow Creek, and the Lochsa to Fire Creek. Some 500

miles of this large river system remain to be examined.

Stream surveys were also started on the Klickitat River but only 38 miles had been surveyed when winter weather conditions forced the termination of the survey for the season.

A total of 1,177 miles of stream was surveyed during the season. Information obtained from these surveys was made available to

various interested agencies.

Salmon redds and spawning habits.—An investigation was undertaken to study the spawning habits of spring and fall chinook, silver, and chum salmon as an aid in interpreting the results of the stream survey. The information gained as a result of this investigation is as follows: (1) The space required for each pair of spawning fish, (2) type of gravel selected, (3) depth of water preferred, and (4) temperature prevailing at the time of spawning. In addition, case histories of individual redds were recorded, including data on the longitudinal and horizontal measurements of the redds, the time of the male intervention, the deposition of the ova, and superimposition and succession of the redds. These studies were conducted in the Kalama, Ohanopecosh, Toutle, Grays, German, Abernathy, and Alochaman Rivers.

During the period of investigation information was obtained on 486 salmon redds in these rivers. The results of this study are now being analyzed and a report for publication will be submitted in the

near future.

Tagging.—A series of 25 tagging experiments were conducted in the Columbia River on spring and fall chinooks which pass through the fishery from May 1 to the latter part of August and early Sep-The purpose of these experiments is to obtain data on (1) . the rate of migration of the salmon upstream, (2) their distribution in the river system, (3) their appearance at hatcheries, and (4) some estimate of fishing mortality. These experiments will contribute invaluable information as a basis for regulation of the fishery and for stocking policies.

The experiments were carried out at three localities on the river, Sand Island, Woody Island, and in the vicinity of Oak Point. These points are located 5, 25, and 45 miles, respectively, from the mouth of the Columbia.

During these operations 2,357 chinooks were tagged and liberated, of which 743, or 31.5 percent, were recovered from the commercial fishery, sport fishery, hatchery, and from the spawning grounds. The recovery from hatcheries was 48 tags, or 2.04 percent.

Information was obtained on the distribution of the spring chinook run in the tributaries of the Columbia, indicating that fish entering the river in the month of May are destined for tributaries in the Upper Columbia, Snake River, and Willamette River systems.

The results of this experiment will be included in a report which is

being prepared for publication.

Construction of fish protective works.—On the 1st of July combination grants of P. W. A. and W. P. A. funds were made available for the construction of fish screens and other fish-protection works on certain Federal power and irrigation projects. These allotments authorized the expenditure of \$50,000 in each of the States of Oregon. Washington, and Idaho, and \$118,000 for the construction of one fish screen in the Wapato Canal of the United States Indian Service near Yakima, Wash., and one screen in the power canal of the United States Reclamation Service near Prosser, Wash. Surveys have been made and plans drawn for screens at the Wapato Canal, Prosser Canal, and Black Canyon Dam diversion of the Reclamation Service in Idaho, remodeling of screens in the Sunnyside Canal near Yakima. Wash., and construction of a screen in the Echo Feed Canal of the Reclamation Service on the Umatilla River in Oregon, as well as for several small projects in the State of Washington. Contracts have been let and work started on the construction of the steel screen drums for the above-mentioned projects. A contract has been made and work is well advanced on the concrete structure for the Wapato Canal screens. Excavation work has been going forward at the Black Canyon Dam site and at the Sunnyside Canal and considerable concrete and steel work has been done as well at Sunnyside. Concrete structures will be built at the remaining sites when the work can be done at the lowest cost and with the least interference with canal operations. This work has been done under the supervision of J. A. Craig and O. W. Lindgren, associate hydraulic engineer.

Special surveys.—An observer was stationed at the dam across the Clearwater River at Lewiston, Idaho, from late spring until late fall to observe the condition of the runs of migratory fish passing that point. It was found that a significant run of steelhead trout still enters the stream, but that salmon are no longer numerous in that watershed. Lack of adequate fishways is apparently the reason for this condition and the owners of the dam have drawn plans for two new fishways and the remodeling of the present single structure. As soon as this construction is completed, several hundred miles of spawning grounds will be made available again to salmon. Collection and tabulation of statistical data relating to catch records and abundance of salmon and steelheads of the river were continued.

COHO SALMON

The coho salmon investigation, the basic objectives of which are a study of the life history of this species under the varying conditions

found in the different streams of the Puget Sound region, the determination of the causes for the decline in its abundance, and the development of methods for rebuilding the runs was continued during

the past year by George B. Kelez.

The series of three marking experiments undertaken during the fall and winter of 1937 at the Quilcene (Wash.) station of the Division of Fish Culture 2 was completed, during the month of May, with the marking of 17,094 coho fingerlings of the 1936 brood. These fish had been held for the purpose of releasing them at the approximate time of normal seaward migration. At the time of this last release, marked individuals from the lots released in September and December 1937 could still be observed in the Quilcene River in the vicinity of the hatchery. It is expected that comparative returns from these experiments will provide further information both on the success of various periods of hatchery rearing and on the relation of the additional costs of prolonged rearing to the increased survival rate of the fingerlings liberated.

No further recoveries of marked fish from the 1935 experiment on Voights Creek, tributary to the Puyallup River, were made during the late winter run, and none were taken from the Green River.²

Several tags from the 1937 Samish River experiment were returned to the laboratory during the spring and summer. This experiment was undertaken to test the practicability of marking fingerlings by the use of an internal celluloid tag in combination with the excision of the dorsal fin, as an alternative to the usual method of marking in which two or more fins are removed. If this method is successful, it will eliminate the present limitation on the number of possible experiments which the number of available fin combinations imposes.

Collections of scale samples and biological data from mature cohos taken in the commercial fishery were made during the season. Samples aggregating approximately 4,500 fish were taken during the summer fishery at Anacortes, Wash., and samples of more than 2,000 fish were taken during the fall fishery at Seattle. Supplementary samples and catch data were collected during the season from the sport fishery carried on in the vicinity of Seattle. Collections of coho fingerlings were also taken during the season from the sport fishery carried on in the vicinity of Seattle and the major streams tributary to Puget Sound.

During the spawning migration regular collections of scale samples were taken and estimates of population size were made on all streams tributary to Puget Sound on the eastern shore. It is believed that variations in early life history, as shown by the scale nucleii, will differ sufficiently between the colder northern streams and the warmer southern ones to afford a means of separating these populations on the basis of scale characteristics. Through a comparison of samples of scales taken from the commercial fishery with those from the two spawning areas, the relative contribution of these districts to the

fishery may be determined.

Observations on the spawning grounds during the fall and early winter indicate that, although the total escapement of cohos was not large this year, spawners were well distributed in all the streams of

the region.

See "Progress in Biological Inquiries, 1937."

BRISTOL BAY SALMON FISHERIES

The Bristol Bay region of Alaska is the greatest red-salmon producing area in the world, providing, as it does, more than 60,000,000 pounds of first quality canned salmon a year. Sporadic studies of the salmon in this area have been carried on since 1922, and information has been obtained on the age and migration habits of some of the populations inhabiting the five major watersheds in this region.

The recent development of extensive offshore fishing has been considered a possible source of serious injury to this salmon fishery. The fact that there is little available knowledge of the life history of salmon in this area, and of the factors affecting the survival of the populations as a whole, made it imperative to inaugurate a thorough biological study of the fish of this region, their migration routes and the factors affecting their survival. An appropriation was made available on July 1 for the purpose of carrying on the first year's study of a 5-year program of investigation. The problems entailed in such an investigation are manifold and must necessarily include studies of a multitude of factors, biological, physical, and chemical, affecting the species from the time the eggs are deposited in the gravels in the upper reaches of the watersheds until the progeny from one year's spawning have completed their life cycle and have deposited the fertilized eggs from which another brood will result.

The investigation separates itself into two distinct though related divisions, the fresh-water and the marine, which are being carried on

by George B. Kelez and J. T. Barnaby, respectively.

Fresh-water studies.—The principal activities of this phase of the investigation consist of the determination of the physical and biological characteristics of the fresh-water areas of the Bristol Bay region, the evaluation of the annual spawning populations, age analyses of the runs in the various rivers, and the measurement of factors influencing the mortality of the eggs and young fish in fresh water.

During the past season reconnaissance surveys of the five main river systems of the region were made, in which the general topographical features of the watersheds, the number and size of the headwater lakes and tributary streams, and the extent of the spawning areas were noted. From these observations thorough surveys of important spawning grounds have been planned and areas selected for carrying on marking experiments, migrant collections, and similar studies.

A number of small lakes, typical of the particular watersheds in which they lie, were inspected, and several suitable ones chosen for studies of the biological characteristics of the environment in which the young fish grow and develop. Here, also, the effect of varying climatic conditions on the survival of the stocks may be determined.

Methods of handling the commercial catch at the canneries were observed and plans were made for a complete annual program of random sampling of the catch in which scale samples will be taken for age analysis. Data on size, weight, and sex ratio will be obtained for population studies. These collections will be supplemented by similar sampling on the spawning grounds of each river system. From this material the age-group composition of each year's run, the

total return from each season's spawning brood, and the selective

effects of the commercial fishery may be determined.

Marine studies.—The sockeye salmon, after migrating seaward, spend 2 or 3 years in the ocean and then return to fresh water to spawn. During this period they make over 98 percent of their growth in weight. Hence, environmental factors affecting the fish during their stay in salt water have a most important part in determining the condition and quality of the mature fish.

The United States Coast Guard very generously cooperated with the investigation by furnishing one of their large cutters, the *Red*wing, for the purpose of conducting an oceanographic survey of the waters of Bristol Bay and the contiguous waters in which salmon live

during their ocean sojourn.

The program of oceanographic studies followed the general methods used by Dr. T. G. Thompson, Director of the Oceanographic Laboratories at the University of Washington, who has been making oceanographic studies of the North Pacific Ocean for a number of years. In this way the data will be in proper form for comparison

with the results of the general survey.

During the season the entire area of Bristol Bay proper, comprising over 10,000 square miles, was crossed and recrossed and samples were collected at 164 stations. The oxygen and salinity content of the water were determined and temperature data collected for the purpose of calculating the direction and force of the ocean currents. As a corollary to these studies current meters were operated at various depths and data were collected on the type of bottom and the depth of water at each station. Plankton samples were collected to determine the type and abundance of food present for the fish.

The oceanographic surveys are to be continued and the migration routes of the fish are to be determined by extensive marking, tagging, and sampling programs. These data will also furnish information

on the fluctuations in ocean mortality.

KARLUK RIVER RED SALMON

The investigation to determine the extent and causes of the fluctuations in the size of red salmon runs in Karluk River, Alaska, was continued in 1938 by J. T. Barnaby and Allan C. DeLacy. Field work was carried on from early April until the end of September.

Population studies.—The commercial catch of Karluk red salmon was sampled throughout the season to discover marked fish returning from marking experiments carried out in previous years. During the season 305,283 salmon were examined and 1,481 marked fish were found. The purpose of these experiments is to determine the mortality of the fish during their stay in the ocean. The results to date indicate that ocean mortality is fairly constant and that the variations in the ratio of return to escapement are mainly due to fluctuations in the environmental conditions affecting the fish during their stay in fresh water. The returns of marked fish during the past season were mainly from the experiments of 1936, in which year 26,700 fingerlings were marked by excision of the adipose and right ventral fins and 26,700 by excision of the adipose and both ventrals. Thus, in addition to the basic information desired, these experiments

served as a check on the relative value of the different marks used. Recoveries of fish in which only one ventral had been removed amounted to 663, while recoveries of the fish in which both ventrals had been removed totaled only 569. Apparently the fish marked by removal of the adipose and both ventrals had a lower survival value than did the other group. While complete returns from this experiment will not be at hand until 1940 these results indicate that caution should be exercised in comparing marking experiments in which different combinations of fins have been removed.

A counting weir was again operated in the Karluk River to determine the number of fish going up the river to the spawning grounds. Counting was continued until September 3, at which time 875,678 red salmon and 1,639,589 pink salmon had passed upstream. Owing to the large number of dead spawned-out pink salmon drifting downstream the weir had to be removed on September 4. While the escapement figures are consequently not quite complete, they are of considerable value. Data on the escapements and the returns from given escapements have been collected for a number of years and it is important that no breaks should occur in the series of data.

More than 11,500 scale samples were collected during the season for the purpose of calculating the age group composition of the escapement and the commercial catch. The number of fish returning from each brood year is determined in this way and credited to the proper year. This study is of basic importance because it indicates what variations may be expected in the returns from known escapements and what is the optimum sized escapement for this and other

watersheds of a similar magnitude and nature.

Ovaries from fish ranging in size from 20 to 24 inches were preserved and counts are being made to determine the number of eggs produced by each fish. The results of the present investigation will be compared with similar work done in 1926 to determine whether or not any change is taking place in the fecundity of the species.

The seaward migration of red salmon fingerlings began on May 26 and continued intermittently until June 16. For the purpose of determining the age composition and the length frequency of the various age groups making up the migration, samples were collected on all days the migrants were in the river. The migration appeared to be of average magnitude and the fingerlings were of the usual

strong, sturdy stock so characteristic of this watershed.

Predatory species.—As the char Salvelinus malma, or Dolly Varden trout, is very abundant in the Karluk watershed and is considered to be one of the most important salmon predators, a study of this species is being carried on in conjunction with the studies of the salmon population. In 1937 a series of marking and tagging experiments were initiated to aid in determining the size, homogeneity, growth rate, migration habits, and mortality of the population of chars inhabiting the Karluk River and Karluk Lake. During the past year three more experiments were started, in which external tags were used in lieu of the internal tags used in the 1937 experiments. To recover the internal tags and discover the distinguishing number it was necessary to kill and dissect the fish. The external tag has a marked advantage in that a recaptured tagged fish can be identified by the number on the tag, measured, and then released. Recaptures of chars from these experiments are conse-

quently expected to extend over several years, permitting accurate

determination of growth and longevity of the species.

The results obtained from the 1937 and 1938 tagging experiments show that: (1) There is a slight amount of straying from one watershed to another but on the whole the chars return in the fall to the same streams from which they entered the ocean. (2) Many, if not all, of the chars that migrate seaward in the spring, return to fresh water in the fall of the same year and migrate seaward again in the spring of the following year. (3) There are at least two populations of chars in the Karluk watershed, those that live in Karluk Lake and those that live in the river. However, these populations mix to some (4) The chars in Karluk Lake do not comprise a homogeneous population but are apparently divided into several rather distinct groups which intermingle to a slight degree. (5) The chars in this watershed have a relatively slow growth and are relatively long lived. (6) Sea-run chars make a faster growth during the time they are in the ocean than do the non-sea-run type during the same period of time. (7) Sea-run chars, on the average, make no growth in the 8- to 9-month period spent in fresh water between the upstream migration of one year and the downstream migration of the following year. Length-weight measurements made in the spring, and again in the fall, have shown that there is a marked difference in the condition factor of the downstream and upstream migrating chars. During the few months spent in the ocean these fish increase in weight from 60 to 100 percent, and about two-thirds of this weight increase is lost between the time of the upstream migration of one fall and the time of the downstream migration of the following This loss in weight is attributable to the fact that these fish spawn during the period spent in fresh water and also in part to the limited food supply available during the winter months.

A cooperative observer's meteorological station was installed at Karluk in the latter part of June 1937. Data for the first fiscal year were complete by June 30, 1938. The collection of these data is of considerable importance in view of the marked effect climatic conditions have on the survival of salmon. The average monthly rainfall was 2.77 inches, the total for the fiscal year being 33.26 inches. There were 110 clear days and 255 cloudy or partly cloudy days. There was precipitation on 149 days. The highest air temperature during the year was 66° F. and the lowest was 6° F. The yearly mean

average was 40.3° F.

PINK SALMON

The pink-salmon investigation during 1938 dealt with the factors contributing to the change in abundance and the time of appearance of the pink-salmon runs in Southeastern Alaska. This investigation was carried on by Dr. F. A. Davidson and Samuel J. Hutchinson. The work was confined to a study of the pink-salmon runs in Southeastern Alaska which comprise the bulk of the Alaska pink-salmon catches. The total 1938 catch fell below previous yearly packs and, according to all indications, the runs are maintaining themselves with difficulty under the intensive commercial fishery. If the condition of the runs is not improved in the very near future, drastic measures will have to be taken to rehabilitate these salmon populations or they will soon fall to a dangerously low level of abundance.

Studies pertaining to the continuation and well-being of the pink-salmon runs in Alaska were conducted at the Biological Station in Seattle and the summer field station at Little Port Walter, Alaska. The field station was opened on June 21, 1938, and continued in operation until October 20, at which time the season's work was completed. A number of factors pertaining to the life history were investigated, and stream surveys and other types of aquatic biological studies were carried out.

A tagging experiment was conducted to determine the migration routes of pink salmon passing through Lower Chatham Strait, Alaska. Some 2,095 mature pink salmon taken from the commercial fish traps in Tebenkof Bay, Kuiu Island, were tagged and released. Of the total number tagged, 637 were recaptured by the commercial fishery, a return of 30.4 percent. The experiment is to be repeated in the summer of 1939 and when all recovered tags are collected, information will be at hand covering the routes of migra-

tion taken by both the even- and odd-year pink-salmon runs.

The salmon-counting weir was installed across the stream at Little Port Walter, and a sexing pen was constructed in front of the counting gate to determine the number of male and female salmon in the run. The first of the run passed through the weir on August 28. This was the latest date for the appearance of the run since the installation of a counting weir at Little Port Walter, the run being a full week after the latest observations previously recorded. The males entered the stream in greater abundance during the early part of the season, but by the close of the season the females had almost equaled their number. A total of 3,283 males and 3,184 females entered the stream, bringing the total to 6,467 salmon on September 22, the close of the season. Previous weir-count totals of salmon entering the stream at Little Port Walter have consisted of 6,952 pink salmon in 1934, 6,073 in 1935, 5,164 in 1936, and 7,085 in 1937. From these figures it would appear that the run has been able to maintain itself at a more or less fixed level of abundance in this locality during the past 5 years.

After the adult salmon had entered the stream to spawn, a series

After the adult salmon had entered the stream to spawn, a series of gravel samples were taken from 28 nests of spawning fish to determine the size and type of rubble selected. In computing a percentage mean for each gravel size, and using all of the samples, it was found that 6.38 percent was 3-inch gravel or over; 5.79 percent was 2½-inch gravel; 8.38 percent was 2-inch; 10.80 percent was 1½-inch; 14.82 percent was 1-inch; 7.57 percent was ¾-inch; 12.75 percent was ½-inch; 8.76 percent was ¼-inch; and 24.76 percent was sand aggregate that passed through a ¼-inch screen. Nesting areas composed of gravel over 3 inches in diameter are not selected when areas of the finer aggregate are available, but, owing to crowded conditions, nest building and spawning sometimes take place in

large rubble.

In February 1938, a C. C. C. camp was moved from Juneau, Alaska, to Little Port Walter, under the supervision of the Forest Service. C. C. personnel worked at the station all spring and summer clearing ground, building a dock and float, moving buildings to higher ground, constructing 3 miles of forest trail, and building two shelter cabins on the headwater lakes at Little Port Walter.

On July 22 and 24 the Forest Service, Bureau of Fisheries, and C. C. Č. personnel cooperated on an experimental trout planting program through the use of aeroplanes. Rainbow trout averaging 10 inches in length were flown from Sashin Lake, back of Little Port Walter, to Blue Lake near Sitka. Other plantings were flown to a number of lakes south of Red Bluff on Baranof Island. The C. C. C. camp completed its program at Little Port Walter by the first of

September and was moved to Port Alexander.

The cooperative observer's meteorological records were continued during 1938 at Little Port Walter. Through these records it is possible to measure the climatic changes that have a direct effect on the salmon's fresh-water environment. An anemometer and a psychrometer were installed as additional equipment to measure wind and humidity which indirectly play a part in the salmon's life cycle. A total of 264.53 inches of rain fell during 1938 at Little Port Walter, which is an average of 22.04 inches per month. Rain was recorded on 261 days. The highest air temperature was 71° F., and the lowest was 13° F., with a yearly mean average of 43.08° F. Fifty-five clear days, 58 partly cloudy, and 252 cloudy days were recorded at the station during 1938.

ALASKA SALMON STATISTICS

Collection, tabulation, and analysis of the daily catch records from the various types of fishing gear operated by the salmon fishery in Alaska were continued in 1938 by Elizabeth Vaughan. All available catch records have been collected, and the files will be kept

up to date in the future.

Analysis of these data consists mainly in determining average daily catches for each type of gear throughout each fishing season by districts. Indices of abundance and seasonal time of appearance of the salmon runs are determined from these daily averages. During the past year, the trap-catch records for 1937 in both Prince William Sound and Southeastern Alaska were analyzed and added to the previous compilations. This information, as in the past, was used as a basis for recommending changes in the fishing regulations in Alaska in order to provide for the conservation of the salmon resources. During the past year the gill-net records from the Bristol Bay area have been compiled for all years for which data are available.

From practically all parts of Alaska, fishermen and cannerymen have reported that pink salmon were very late in appearing during the 1938 season. It was felt that this phenomenon was unusual in all areas except Southeastern Alaska, where it was claimed the runs have been steadily getting later. Because of this belief, the industry demanded a revision of the fishing regulations. tistics of the fishery, as collected and analyzed by this investigation, permitted an explanation of this phenomenon and a defense of the present regulations, which were embodied in a series of articles for publication in a commercial fishery journal.

The explanation of the change in the time of appearance of the Southeastern Alaska pink-salmon runs was made on the basis of the correlation between the abundance of the salmon, their average

size, and the time of their appearance in the season.

HERRING

Investigation of the herring fisheries of Alaska was continued in 1938 by E. H. Dahlgren. Mr. Kolloen, who was assigned as a permanent assistant in this work beginning in July, carried out the field work of catch-record collection and of obtaining data on the size and age composition of the populations in the Kodiak and Prince

William Sound areas during the season.

Previous tagging experiments have established the fact that, while the herring populations of Southeastern Alaska are divided into a series of separate populations, there are certain areas, notably at Warren Channel and at the west coast of Kuiu Island, where two of the major populations intermingle on the feeding grounds. The electronic detector was operated to search the fish taken for frozen bait from the Sitka spawning area during the spring. Only two tags were recovered, owing to the decline in the age class which had supported the fishery for the previous 4 years. The younger fish, which were available to the bait fishermen this spring, had not been available for tagging during the previous seasons. Nevertheless, the recovery of these two tags, affixed in previous years at this spawning area, definitely established the fact that the herring return to the same grounds year after year to spawn.

A controlled tagging experiment was carried on at the station at Little Port Walter in order to determine the maximum size of tag which a herring may carry without causing undue mortality. If it is proven that a tag of considerably increased mass can be carried, the difficulty of recovery will be greatly reduced. After an initial heavy mortality the herring appear to survive with a minimum of loss. However, the mortality increases in direct ratio to size of tag, with the largest tag showing an 87 percent mortality as compared to 34 percent for the smallest and 20 percent for the controls at the end of a 2-month period. The experiment is being continued through

the winter with the watchman maintaining the records.

The Southeastern fishery declined to an all-time low since its great expansion in 1927. Since that year the fishery has depended, in some seasons almost exclusively, on the population which spawns in the vicinity of Sitka and which migrates during the summer to Cape Ommaney to support that fishery, and to Warren Island and the west coast of Kuiu Island, where it mingles with the population which spawns at Craig. Studies of the age composition of this population show the almost total failure of three successive brood years; that of 1932, 1933, and 1934. These failures, together with a too intensive fishery, caused a decline of this stock to a dangerously low level.

The measure used in evaluating the abundance of this population is a comparison of the catch per unit of gear per day's fishing, with the average catch per day's fishing established over a 9-year period. In deriving these indices the fleet has been divided into two groups (those of over 35 net tons and those under this capacity) to minimize the difference in efficiency of the larger and smaller vessels. The index for the 1938 season for the large vessels was 35, as compared to 71 for 1937 and 140 for the optimum season of 1932. The indices for the smaller vessels were 41 for 1938 as compared to 75 for 1937 and 164 for the optimum 1932 season. On the basis of these findings,

a closure of the Cape Ommaney area was recommended until the population shows definite signs of rehabilitation. The dangerously low level to which this population has been reduced was further evidenced by the failure of the normal number of spawners to appear at the Sitka area, which usually has had a large area heavily spawned.

The fishery in the Prince William Sound and Kodiak areas continues at a high level of abundance, as shown by continuing high yield and large catches per unit of gear. These areas are not yet as intensively fished as is Southeastern Alaska, but considerable expansion is contemplated in each area, and a close watch must be maintained to avoid over-exploitation and consequent depletion.

PACIFIC PILCHARD INVESTIGATIONS

O. E. Sette, in charge

After 6 years of rapid and sustained increase in the total yield, the Pacific coast pilchard fishery experienced sharp fluctuations between 1937 and 1939. The season of 1937-38, for example, ended with a catch of 415,583 tons, which was 36 percent less than had been taken the previous year. In Washington and Oregon, on the other hand, though the summer season of 1938 was shorter than that of 1937, the total catch was greater than in any previous year, being 40,000 tons, or about 18 percent more than in 1937. Likewise, the fall season of 1938-39 in California was relatively successful, yielding by the end of 1938 a catch of 530,452 tons, which was 61 percent higher than that of the corresponding period of the previous year. Though other fluctuations had occurred during the relatively short history of the pilchard fishery, the sharp drop of last year's catch, following as it did an intensification of the fishery, caused concern among many as to the state of abundance of the pilchard stock. That there are fluctuations in the availability and even abundance of the stock, however, is one of the many elements that makes the problem of appraising the condition of the pilchard resource so elusive and complex.

This is a problem on which several organizations have been working for a number of years, namely, the fish commissions of California, Oregon, Washington, and British Columbia. In October 1937, the United States Bureau of Fisheries established a laboratory at Stanford University to cooperate with these agencies, to assist in the coordination of their results, and to investigate those features needed to supplement their findings. In May 1938, a conference of biologists, representing all the institutions working on pilchard research, was held at Stanford University. Past and current in-

vestigations were discussed and plans laid for future work.

Up to the end of 1937, a considerable body of information had been collected bearing on the migrations, spawning, age, and growth of the pilchard. Tagging experiments have demonstrated extensive migrations along the coast for as great a distance as between California and British Columbia. The spawning season has been determined in California, the principal spawning grounds surveyed, and the egg and larval stages described. The phenomenon of fluctuating year classes has been well established, individual dominant year classes having been recognized and traced through several years.

The basic problem remaining for solution is this: What is the optimum level of catch below which the stock would go to waste through underutilization, above which it would become reduced to commercial unimportance through overexploitation? Before this level can be determined, three questions must be solved: (1) How much is the stock reduced by the fishing? (2) How has the relation in the stock of income to outgo changed during the growth of the fishery? (3) How much does fishing in specific areas affect the stock in other areas?

Answering these questions necessitates the determination of abundance, age, reproductive success, and of the importance of intermigration. These necessities determined the program of the South Pacific Investigations during 1938.

STUDIES OF ABUNDANCE

Since the conventional method of estimating abundance from the performance of fishing fleets is limited to the range of fishing operations, attempts were made to measure directly the size of the pilchard population by aerial observations. This work, done in planes of the United States Navy and Coast Guard from January to May, covered an aggregate of 13,000 miles of flying distance, extending from Cape San Quentin on the south to Santa Barbara on the north. and several hundred miles to sea, and covering the more important schooling grounds of the pilchard a number of times. Although schools were sighted frequently and identified as pilchards, it was found to be unfeasible to estimate their size because their limits could not be defined. Also, judging from the time and places of occurrence, it was concluded that they did not appear near the surface by day in proportion to their abundance. Night observations were even less satisfactory, and the aerial method had to be abandoned.

Consequently, a measurement of changes in relative abundance by an analysis of the commercial catch, begun in 1937, took on added importance. The catches of boats delivering pilchards to the floating reduction plants, operating off San Francisco since 1931, were made available for this purpose by the plant owners; and the shore landings of the fleet considered were furnished by the California State

Fisheries Laboratory.

Obviously, the boat catches alone are not directly indicative of the availability or abundance of the fish, for the activities and success of fishing boats are modified by the weather, the number of hours of darkness, since pilchard fishing is carried on in California only in the dark, and by other less tangible influences. Consequently, it was necessary to treat the data statistically so as to account, as far as possible, for the effects of these influences. Transcription of the records was completed and the analysis was under way during 1938. It is anticipated that a report on this subject will be completed in 1939. The findings in relation to comparable work being carried on for the ports of Monterey and San Pedro by the California State Fisheries Laboratory, and for Oregon and Washington by the Fish Commission of Oregon, should answer question 1.

AGE AND GROWTH

The second question can be answered by determining the ages of the fish making up the population each year, thus learning the relative abundance of the individual broods of previous years (income) and how fast they are removed by fishing and by natural mortality (outgo). To begin with, the relationship between age and size must be established. Once that is done, the findings can be applied to past records to detect any changes in the balance between income and outgo.

Age determination is being attempted by interpreting marks in hard structures, by observing the growth of young pilchards, and by identifying modes in frequency distributions of the adult population. During 1938, a series of frequency curves of young fish measured in southern California was collected, from which the growth rates of the first two or three age classes may be traced. A sample of young was also collected for comparative purposes at Magdalena Bay, Lower California, and others from Coos Bay, Oreg., and from various points in Washington.

Scales and otoliths were collected through the year from the young fish samples. Most of these, numbering over 10,000, have already been mounted by a W. P. A. project, and they are now being studied to learn the time of appearance of a year-mark and the extent to which pilchard scales can be used for age determination. During 1938, sampling of young fish was carried on at San Pedro, Newport Beach, This work will be continued in 1939 so as to comand San Diego.

plete at least one year's cycle of growth.

For studies on various phases of the biology of the commercialsized fish, the South Pacific staff sampled the catch at Grays Harbor during the summer at Washington, and during the subsequent fall and winter at San Francisco. In addition to age and growth studies by analysis of the frequency curves, these data will be examined to determine the extent to which the populations of the two regions can be identified with each other. The work will be much facilitated by comparable samples from Oregon, taken by the Oregon Fish Com-

mission. A history of the size composition of the pilchard population in California, going back almost to the beginning of the fishery, has been kept by the California State Fisheries Laboratory, whose staff has sampled the catch systematically since 1919. Thus is recorded the rise, growth, and decline of the various dominant year classes that have appeared since then. This vast amount of data is being made available to the South Pacific Investigations for use in connection with current studies. During the year part of these records have been transcribed to a punch-card sort system. Through the aid of a W. P. A. project, it is expected that the remainder of the transcription will be completed during 1939. The records will be treated statistically in an effort to recognize homologous component age groups, to measure the rate of their removal, and hence to compare the effect of the lower fishing intensities of former years with higher current intensities.

EARLY LIFE HISTORY

The study of the data on size composition has already shown a relation between temperature and incoming successful year classes, warm years being associated with their appearance in the fishery 3 years later, cold years with their nonappearance. A report on this subject was prepared during 1938 for publication.

Further investigation of the relation between temperature, or other environmental elements, and successful year classes should make it possible to predict 3 years in advance the relative size of year classes, and hence facilitate greatly an intelligent management of the fishery

from the conservation as well as industrial viewpoint.

Such knowledge requires a boat for the quantitative sampling of the young during their stages of random distribution, and for the study of conditions on the actual spawning and nursery grounds. For 1939, arrangements have been made with the Scripps Institution of Oceanography for a joint expedition on the research boat E. W. Scripps during May and June off the coast from California to British Columbia. The northern and western limits of the spawning range of the pilchard will be sought by the Bureau. Parallel observations on the hydrographic conditions will be made by Scripps Institution. This first cruise must of necessity be of a preliminary nature, and can be of far-reaching significance only when related to cruises made in other years and covering the entire pilchard-spawning season. It seems unlikely that such a program of marine work can be carried out unless a boat is at the year-round disposal of the investigation.

ORIGIN OF THE COMMERCIAL SUPPLY

To determine whether the stock in northern waters is self-perpetuating, young pilchards were sought along the Washington and Oregon coasts during the year. The stomachs of salmon and albacore, both predaceous, which presumably feed to some extent on pilchards, were examined at frequent intervals between March and December. In this manner young fish were found in April and, later, additional ones were collected by a beach seine in Willapa Bay, and others in a trap at Coos Bay. Though these collections may indicate some spawning in northern waters, the importance of such spawning in perpetuating the population found there is yet to be investigated.

It is hoped to appraise the contributions from various spawning areas through study of the sculpturing on the scales. Preliminary examination has shown that the spacing of the ridges on scales appears to differ among young fish caught in different localities. If further work confirms preliminary observations, this would be a characteristic established early and preserved throughout life. It would constitute, in effect, a marking on the fish according to areas of origin, and suitable interpretation of it would provide an answer to question 3. This will require additional collections of young fish during 1939 in various localities from Mexico to British Columbia. The studies on the scales will be continued so as to determine the significance and utility of ridge measurements and age determinations.

The program of work was carried out by a staff consisting of O. E. Sette, in charge of the investigations, Dr. L. A. Walford,

Kenneth Mosher, Ralph Silliman, and Earl Palmer. The prosecution of these investigations over so large an area was made possible by the cooperation and assistance of several organizations and persons. Stanford University contributed spacious laboratories for the central office, and extended the privileges of the University to staff The California Institute of Technology provided space for the southern field station at its marine laboratory in Corona del Mar. The California State Fisheries Laboratory furnished records essential to various phases of the work. Various branches of the Government service gave much valuable cooperation during the year. The aerial observations were carried on in planes of the United States Navy and Coast Guard. Space was provided a member of the Bureau on board the United States Coast Guard Cutter Hermes for experimental work on collecting apparatus at sea and for a cruise to Magdalena Bay, where samples of young fish were obtained. Also, the Coast Guard, as well as the United States Weather Bureau, furnished weather data for points along the Pacific coast. During the year the staff enjoyed the advice of members of these organizations, particularly of Drs. Frank W. Weymouth, Willis H. Rich, and Hugh H. Skilling of Stanford University, and Lt. Comdr. C. W. Thomas and Lts. S. C. Linholm and W. E. Sinton of the United States Coast Guard. The extensive sampling of the catch was made possible by the willing cooperation of members of the fishing industry from San Diego to Seattle.

GREAT LAKES FISHERY INVESTIGATIONS

DR. JOHN VAN OOSTEN, in charge

The critical depletion of the more valuable commercial species continues to be the major problem of the Great Lakes fisheries. The extent of this depletion is apparent from comparison of the present-day production of certain species with that of earlier years. As an illustration, if normal production in Lake Michigan is given an index value of 100, the present productions of important species are as follows: Wall-eyed pike, 62; lake herring, 59; lake trout, 58; whitefish, 58; yellow perch, 43. Similarly, the production indexes of perch and chubs in Lake Huron are only 44 and 36, respectively, and the production of the renowned Lake Superior whitefish is only 10 percent of normal. The preceding examples are only representative; in Lake Erie the production of nearly all important commercial species is without question on the decline, and the present total production of Lake Ontario is only 20 percent of normal.

The downward trend in the production and abundance of important commercial species of the Great Lakes has by no means reached its limit, except, of course, for such forms as the sturgeon, the Lake Ontario bloater, the blackfin of Lakes Michigan and Huron, the bluefin and longjaw of Lake Superior, and the Lake Erie cisco, all of which have become commercially unimportant. With most species, present conditions represent only a stage in a process of depletion that will certainly lead to the complete ruin of the fishery unless immediate and drastic measures are taken to halt present

As proof of the contention that depletion is even now proceeding rapidly, it may be pointed out that trout fishermen of Lake Superior

have found it most difficult to operate at a profit during the past 2 seasons; that the production of whitefish in Lake Michigan dropped to an all-time low in 1936 and failed to show significant improvement in 1937; that the production of chubs in the State of Michigan waters of Lake Michigan decreased more than 40 percent from 1935 to 1937; that the 1937 production of whitefish in Lake Huron was only 1,120,000 pounds as compared to a 1930-34 average of 3,394,000 pounds; and, finally, that the production of yellow perch in Lake Erie decreased from 14,219,000 pounds in 1934 to 2,051,000 pounds in 1936. It is true that the production of some species has at times shown temporary improvement, but these increases have merely constituted irregularities in the general downward trend.

Decades of bitter experience have demonstrated conclusively that the depletion of Great Lakes fishes cannot be halted under the present system of divided control, in which each State frames its own laws

for the regulation of the fisheries within its boundaries.

The possibility that adequate and uniform regulations for Great Lakes fisheries will ultimately be attained was increased greatly in 1938 by the active support of two influential organizations, the Council of State Governments and the National Resources Committee. At a Great Lakes Fisheries Conference called by the Council at Detroit February 25–26, 1938, a resolution was adopted recommending the establishment, by treaty with Canada, of an International Board of Inquiry into conditions of the Great Lakes fisheries. A Special Committee on Lake Michigan Fisheries was organized and held its first meeting at the time of the Great Lakes Conference. The Special Committee held a second meeting in Chicago on May 6.

Both the Great Lakes Committee and the Special Committee on Lake Michigan Fisheries held meetings in the late autumn in Chicago, at which time they reviewed progress made during the year and elaborated their program for coordinated action by Canadian, Federal, and State agencies. As an immediate goal both committees will attempt to secure the enactment of discretionary power acts whereby the conservation departments of the several Great Lakes States will be authorized to regulate Great Lakes Fisheries by executive order.

The appointment of Dr. Van Oosten in October 1938, to membership in the Water Resources Committees, of the National Resources Committee, of the Upper Great Lakes (Superior, Michigan, and Huron) and Lake Erie basins marked the first representation of Great Lake fisheries interests on these committees. Dr. Van Oosten was later made a member of a subcommittee of each of the basin committees on water as related to industry and navigation. The Upper Great Lakes and Lake Erie Basin Committees plan to cooperate fully with all agencies interested in the development of a sound conservation program for Great Lakes fisheries.

An executive order drawn up by the Wisconsin Conservation Commission and signed by the Governor on January 21, 1938, constituted an outstanding advance in the regulation of Great Lakes fisheries. The order contained provisions for substantial increases in the mesh size of commercial gear and in the size limits of lake trout and white-fish in the Lake Michigan waters of the State. These changes, which brought the Wisconsin regulations nearer the standards maintained by the State of Michigan, are an important step toward the attain-

ment of uniform regulations for all Lake Michigan waters.

The activities of the Great Lakes staff were again characterized by active cooperation with State and Federal officials and with sport and commercial fishermen. Certain of the cooperative projects will be described later in this report. During the year Dr. Van Oosten acted in an advisory capacity at 19 meetings and conferences in which Great Lakes fisheries problems were under consideration. He also continued to assist State conservation officials in the drafting of proposed fisheries regulations.

The Bureau gratefully acknowledges the cooperation of the University of Michigan in providing laboratory space and extending

numerous other courtesies to the staff.

STUDIES OF ABUNDANCE

Dr. Ralph Hile has completed the routine computation of 1937 indexes of production, abundance, and fishing intensity for important commercial species in each of the 20 statistical districts of the State of Michigan waters of the Great Lakes. The assignment of a W. P. A. project to the Great Lakes laboratories has made possible the tabulation of valuable production statistics for the several fishing districts over the 18-year period, 1891-1908. These compilations are being made from original records loaned to the Bureau by the Michigan Department of Conservation.

AGE AND GROWTH STUDIES

Lake Huron whitefish .- A study (in press) of the Lake Huron whitefish, Coregonus clupeaformis, by Dr. Van Oosten included information on growth rate, growth compensation, the age and yearclass composition of the stock, the sex ratio, age at maturity, the relationship of total and standard length, the length-weight relationship, and the coefficient of condition. The Lake Huron whitefish grows most rapidly in the first year of life, but a secondary period of rapid growth occurs in the fourth year. Growth compensation occurs during at least the first 7 years of life. The collection of the summer of 1923 was dominated by age-group IV (1919-year class), and the fall collection of 1924 was dominated by age-group VI (1918year class). The sexes were equally abundant in the collections as a whole, although the males tended to become relatively less numerous with increase in age. Sexual maturity was attained by nearly all males in the fifth year and by females in the seventh year. A single curve was found suitable to express the length-weight relationship of both males and females. There was, nevertheless, a noticeable tendency for females to be heavier than males of the same length, and for whitefish taken in the summer of 1923 to be in better condition than those collected in the fall of 1924.

Lake Champlain whitefish.—A paper entitled "The Age, Growth, and Food of the Whitefish of Lake Champlain" by Drs. Van Oosten and Deason is now in press. The materials consisted of scale samples and records of weights and measurements of 120 whitefish taken in northern Lake Champlain in 1930, and 175 individuals taken in southern Lake Champlain in 1931, and of the stomachs of 141 whitefish, also collected from southern Lake Champlain during the fall of 1931. The data suggested that the natural size and age compo-

sition of the Missisquoi Bay population was disturbed by the early fall seining of 1930. The size and age distribution of the southern Lake Champlain fish indicated that no disturbance through exploitation had taken place. The two populations were more or less distinct also as to growth rate, the length-weight relationship, and the location of spawning grounds. Autumn is apparently a season of reduced feeding activity, for 86 percent of the 141 stomachs examined were empty. The food consisted almost exclusively of invertebrates (99.1 percent) which were made up principally of mollusks (92.8 percent).

Lake Erie yellow perch.—Mr. Jobes has completed the preliminary draft of a manuscript on the growth of the Lake Erie perch. Much of the information obtained in this study has been presented in past reports. The most important new development was the determination of a method for the calculation of growth from scale measurements. Lengths at the end of the second and later years can be computed by direct proportion, that is, on the assumption that the body-scale ratio is constant. First-year lengths, however, must be determined from an empirical curve of the body-scale relationship.

SPECIAL SURVEYS

Red Lakes and the International Lakes.-At the request of the Office of Indian Affairs of the Department of the Interior, Drs. Van Oosten and H. J. Deason conducted a 3-week survey of the fisheries of Upper and Lower Red Lakes in northern Minnesota during late August and early September 1938. The principal purpose of the investigation was to obtain information for the settlement of various controversies concerning the regulation of the commercial gill-net fishery that is conducted by the Indians on Lower Red Lake and by white citizens on Upper Red Lake. The survey included the quantitative analysis of commercial catches as to species and size composition, a study of the variations in the size of gill-net mesh employed. and the collection of biological data for the study of the life histories of the principal species. All available statistical records of the commercial fishery and of the artificial propagation of wall-eyed pike and whitefish were transcribed for later analysis. Conservation and Indian Agency officials, fishermen, and other interested persons were interviewed.

A large portion of the work preparatory to the submission of a formal report has been completed. The report will contain recommendations, largely for the guidance of officials of the Red Lake Indian Agency, for the regulation of the commercial fisheries which constitute one of the principal sources of income for the Indians.

Following the Red Lakes survey Dr. Van Oosten made a brief

Following the Red Lakes survey Dr. Van Oosten made a brief survey of the boundary waters of northern Minnesota and south-western Ontario, at which time he interviewed fishermen, transcribed statistical records, and collected biological data on the principal commercial species.

Potagannissing Bay investigation.—The investigation of the relationship between the sport and commercial fisheries of Potagannissing Bay, Lake Huron, conducted under the joint supervision of Dr. Van Oosten and F. A. Westerman of the Michigan Department of Conservation, has been concluded and a formal report has been pre-

pared. The allegedly harmful effect of the commercial trap-net fishery of the area on the population of game fishes, particularly smallmouth bass, in the region apparently has been overestimated. The occurrence of large numbers of bass in the trap nets is distinctly seasonal and confined to relatively limited areas. Consequently, only minor restrictions on the commercial fishery for coarse fish are necessary in order to afford adequate protection to the game-fish stock. The report contains specific recommendations for the regulation of the fisheries.

Lake Champlain investigation.—The report of the International Fact-Finding Commission, consisting of Dr. Van Oosten of the Bureau and of James A. Rodd of the Department of Marine and Fisheries, Ottawa, Ontario, on fisheries controversies on Lake Champlain was largely completed during the past year and will soon be submitted to the respective governments. The report will contain a discussion of the fisheries controversies, a tabulation and analysis of all available information concerning commercial fishing and angling, descriptions of the natural history of the principal species, a critical historical review of the artificial propagation of wall-eyed pike and yellow perch, and recommendations for the regulation of the commercial and sport fisheries of Lake Champlain. Appendices to the report will contain original studies of the feeding habits of the principal species as independent contributions of Dr. H. J. Deason and F. W. Jobes of the Bureau, and Dr. R. H. M'Gonigle of the Fisheries Research Board of Canada.

SHELLFISH INVESTIGATIONS

DR. PAUL S. GALTSOFF, in charge

Although the difficulties experienced by the oyster industry in past years were greatly alleviated during 1938 by the general improvement of economic conditions in the country, the decreasing supply of good oysters continued to present a serious problem endangering the future progress of the industry. Scientific and technical knowledge concerning the oyster and its method of cultivation shows that this difficulty can be overcome by increased cultivation of oysters, improvement of the quality of oyster meat, and standardization of the raw and canned product offered to the consumer.

Practical application of this principle meets, however, with many legal and technical difficulties. In many States the introduction of oyster-cultural methods on a large scale necessitates the reorganization of existing policies and systems of operation and abandonment of the practice of exploiting natural oyster resources. Personnel capable of directing and supervising oyster-cultural activities is required to introduce systems of cultivation into States where exploitation of the public bottoms has been the traditional method of the oyster industry since its establishment. Inasmuch as the development of methods of oyster culture suited to the varying conditions of local waters depends upon scientific studies of the physiology and life history of the oyster, it is apparent that the accumulation and dissemination of such information among interested persons is of great practical importance to the oyster industry.

Studies on the propagation of the oyster, its cultivation on public and privately owned bottoms, and the protection of valuable fishing

areas against the attacks of natural enemies and pollution have continued to be the principal fields of shellfish investigation conducted by the Bureau in Massachusetts, Connecticut, Virginia, North Caro-

lina, South Carolina, and Florida.

To determine the practicability of various methods of oyster culture suggested by laboratory experiments, steps have been taken to establish experimental oyster beds in localities set aside for this purpose by State authorities. In cooperation with the South Carolina Board of Fisheries and the Works Progress Administration an experimental project of this nature was undertaken in South Carolina. Experiments on the control of starfish were conducted in Long Island Sound and studies of the parasites of the oyster were continued in Beaufort, N. C. The work on pulp-mill pollution in York River was continued with the cooperation of the Virginia Department of Fisheries with the view of determining the chemical nature of the substance present in the effluent which was shown by previous investigation to be harmful to oysters.

PHYSIOLOGY OF THE OYSTER

Propagation.—Since successful propagation depends upon the presence on oyster beds of a large number of specimens of both sexes capable of spawning, the sex changes in the adult oyster present a problem of practical importance to the oyster farmer. Study of this problem was continued by Dr. Galtsoff and staff at the Woods Hole (Mass.) laboratory and at Milford, Conn., where experimental mollusks individually marked are kept in the outdoor tanks. During the first year (1937) 8.0 percent of the males changed to females and 13.1 percent of the females changed to males, total change in either direction being 9.7 percent. In the second year (1938) 11.2 percent of the males changed to females and 12.1 percent of the females became males, total percentage of changes in either direction being Sex reversal among oysters that have already changed their sex occurs much more often. Out of the total of 32 oysters which changed their sex at any time between 1936 and 1938, 22 (69 percent) reversed their sex. The results suggest the presence in the population of a group of animals with unstable gonads.

Development of spawning reactions, which are different in the two sexes and are characterized in females by the rhythmicity of muscular contractions and discharge of eggs through the gills, fails sometimes to keep pace with gonadal changes and results in physiological intersexuality. Some of the sex-reversed males, possessing ripe ovaries, reacted in typically male fashion by discharging eggs through the cloaca. A complete female spawning reaction occurred, however, at the end of the reproductive season, at which time the

intersexuality had disappeared.

Survival and aging of eggs and sperm.—Experiments on fertilizability of eggs and their survival in water after being discharged by the oyster were carried out at Woods Hole by Dr. Galtsoff. It has been found that more than 50 percent of the eggs will cleave if sperm is added after 12 hours, but a very small percentage cleave normally if 24 hours elapse between their discharge and insemination. The life of sperm depends to a certain extent upon its concentration in sea water. In sufficient concentration (0.2 g. in 50 ml. of sea

water) good sperm is still effective after 24 hours. In greater dilution the sperm perishes sooner. These experiments indicate that simultaneous spawning of the majority of adult specimens and crowding of spawners on spawning beds are essential for the suc-

cessful propagation of the oyster.

Respiration.—The study of oyster respiration was undertaken with the view of determining the effect of environmental conditions on this fundamental living process. An understanding of the factors controlling the uptake of oxygen by an aquatic mollusk is especially necessary for the study of its carbohydrate metabolism and of other metabolic processes which result in the accumulation of glycogen, heavy metals, calcium, and other elements which, from the nutritive point of view, are important food constituents of the oyster meat.

Using the metabolism chamber specially designed for this work and employing the technique perfected during the previous summer, Dr. Galtsoff and G. I. Mishtowt carried out a number of experiments studying the effect of lowered salinity and increased CO₂ tension on oxygen consumption. It has been found that in all the experiments with diluted sea water the oyster used an average of 13.6 percent more oxygen in a salinity of 24 parts per thousand than in a salinity

of 32.

Experiments with CO₂ consisted in bubbling this gas through sea water and determining the rate of oxygen consumption. It was found that CO₂ has a depressive effect on oxygen consumption, which begins to decrease with the decrease of hydrogen ion concentration. The maximum effect is obtained at pH 6.0 or lower, the oyster under these conditions using practically no oxygen and presenting all the appearances of being narcotized.

Further plans for this investigation comprise the determination of respiratory quotients of oysters at different times of the year and under various environmental conditions, and a study of the effect

of various pollutants on respiration.

OYSTER CULTURAL STUDIES

Propagation of oysters in Long Island Sound.—The oyster industry of Long Island Sound and adjacent waters depends upon an abundant supply of seed oysters for its perpetuation. Since the rate of survival of Connecticut seed oysters transplanted to other waters is high, and their growth in a new environment is rapid, there is always an extensive demand for them, and seed producing has become a profitable industry of the State. However, owing to the frequent failure of oysters to set, the industry has not been in a position to supply the much needed seed oysters. In addition to the poor natural setting, the destruction of spat and seed oysters by various pests, especially starfish, is tremendous. The protection of young oysters from their enemies constitutes, therefore, another vital problem for the ovstermen. Both problems have been under investigation by Dr. V. L. Loosanoff and James B. Engle at the Fisheries Laboratory at Milford, Conn.

Spawning and setting.—Continuing the investigations begun in 1937, spawning and setting of oysters were observed at a chain of 15 stations extending from Bridgeport to Morgan Point and east to New Haven, thus covering the most important part of the Connecti-

cut seed-oyster producing section. The methods employed in this

study were identical with those used the previous year.

Observations of the past 2 summers on the spawning of oysters in Long Island Sound indicate that, contrary to common belief, spawning may take place at temperatures several degrees lower than 20° C. (68.5° F.). The first spawning of oysters occurred on June 28, far in advance of the expected time and at a temperature of only 16.4° C. (62° F.). The highest temperature recorded on this day at any of our sampling stations, distributed over a distance of 30 miles of the oyster-producing section of the Sound, was 18.3° C. (66° F.). The average bottom-water temperature of all 15 stations was 17° C. (63° F.). To avoid any errors in recording the water temperature, measurements were taken simultaneously with four deep-sea reversing thermometers, their correctness was verified by the United States Bureau of Standards, and the temperature was read by two investigators.

These observations indicate the need for modifying previous methods for predicting the time of spawning which have been based upon the assumption that oysters do not spawn at a temperature below 20° C. It is evident that other factors, undetermined at present, are involved in inducing the spawning of oysters at low temperatures. Until these factors and their role in stimulating the shedding of sex cells is ascertained, no infallible method for predicting the spawning time of oysters living under natural conditions can be advanced.

Throughout the summer systematic observations on the setting of oyster larvae were made at some 37 stations located in different sections of the Connecticut oyster-growing area. In general the setting occurred late and was extremely light. During the course of these surveys information on the condition of oysters and the prospects of obtaining set was supplied to oystermen at regular intervals through a bulletin distributed by the Connecticut Shellfish Commission.

Observations on vertical distribution of oyster set in 1938 fully support conclusions reached during the previous year to the effect that in Milford Harbor setting occurs in the zone extending from the bottom to a point 2 or 3 feet above low-water mark. Above this level to high-water mark, a distance of about 4 or 5 feet, no setting occurs.

Chemical control of starfish.—A method for the control of starfish by chemical means was tested during the year in large-scale experiments in the Long Island Sound area. Early results of these field experiments and of previous laboratory tests indicate that important progress has been made toward effecting the control of the most

important enemy of the oyster in the New England area.

Since mechanical control of starfish on oyster beds is expensive and only partially effective, the advantages of employing some toxic substance for the eradication of these pests have been obvious. Laboratory experiments on the use of calcium oxide, or quicklime, for the destruction of starfish were therefore initiated at the Milford Laboratory in 1937 by Dr. Loosanoff and Mr. Engle. During the spring and summer of 1938 the method was also tested under natural conditions on the oyster beds of Long Island Sound, where starfish are abundant.

In one test where 25 acres of starfish-infested oyster bottom were treated with calcium oxide at the rate of 480 pounds per acre, as many as 80 percent of the starfish were found to be affected by the chemical 1 week after the beginning of the experiment. In an area where 280 pounds of calcium oxide per acre were used, the chemical acted upon 74 percent of the starfish. It is believed that much better results will be achieved when a suitable mechanical method insuring uniformity of distribution of the chemical over the treated area has been developed.

Observations in the Milford Laboratory show that the particles of lime must come into direct contact with the body of the starfish to be effective. Particles of the chemical falling on the upper surface of the starfish imbed themselves in the delicate skin and rapidly cause its disintegration through caustic action. Lesions so created rapidly increase in size, spreading in all directions and involving the delicate respiratory and other structures found on the dorsal surface of the starfish. After several days the lesions penetrate the body wall, exposing the internal organs. Death usually follows very shortly. Starfish which are not hit by falling particles as the chemical is being applied may eventually come into contact with it by crawling on the bottom. Lime spread on the bottom retains its effectiveness for some time.

Laboratory experiments conducted in large tide-filling concrete tanks indicated that coarse grades of lime, even when used at the rate of 3 barrels (840 pounds) per acre, do not cover the bottom evenly but permit many starfish to escape. Finely powdered lime was found to be much more effective, even in concentrations as light as 280 pounds per acre.

To determine the effect of quicklime on other animals, experiments were carried out with oysters, flatfish, and lobsters, which support the

most important fisheries in Long Island Sound.

Oysters which were subjected for a period of 5½ months to a very strong concentration of quicklime survived, although their growth and increase in weight were somewhat retarded. It must be considered, however, that the concentration of lime in the tank was much greater than that expected to be used on natural beds, and that even if such a concentration were used, it would persist only a short time. It appears, therefore, that lime may be used without endangering the oyster population. Seed oysters survived in lime solutions as well as the adult oysters.

Claims that spreading lime over oyster bottoms will restore the normal color of green oysters were not substantiated by field or laboratory observations. Treatment with lime had no effect on the green

color of the oysters.

Large numbers of hard clams, soft clams, and two species of mussels kept in tanks to which a large quantity of lime was added at monthly intervals survived this exposure for a period of 6 months. Mortality among these animals was not noticeably higher than in the control tanks. Field experiments also showed that there was no mortality which could be attributed to the effects of lime among mollusks dredged from the beds where experiments in the eradication of star-fish were conducted.

Experiments performed at the State Hatchery at Noank, Conn., showed that the fry of flatfish will survive for 1 hour in a 1:1000 concentration of lime provided they do not come in contact with solid

particles. In the latter case death quickly results. Experiments with flatfish eggs obtained from the State Hatchery and taken to the Milford Laboratory showed that exposure in concentrations of 1.0 gr. of lime in 250 cc. of water did not materially increase the rate of mortality, but when the eggs were allowed to come in contact with particles of undissolved lime a mortality of almost 100 percent ensued.

Observations on the effect of lime on lobster larvae of the first, second, and third stages were carried out at the Noank Hatchery in June. In the filtered 1:10 solution the larvae of all stages survived for 4 hours. Similar results were obtained when larvae were subjected to a concentration of 1 part saturated lime solution to 2 parts of sea water. However, in a solution of 1 part of lime water to 1 part of sea water, a mortality of about 25 percent resulted at the end of 4 hours. All three larval stages appeared to be affected equally. In a saturated solution of lime all the animals died in 3 hours or less. In this solution the larvae of the first or earliest stage appeared to be the most resistant. Direct contact of lobster larvae with particles of lime resulted in death.

These experiments indicate that the use of quicklime on oyster bottoms should be restricted to seasons when no larvae of commercial species are present in the water, thus avoiding the danger of destroy-

ing them.

Distribution of starfish in Connecticut waters.—In cooperation with the Connecticut Shellfisheries Commission two surveys were made to determine the abundance of starfish on oyster bottoms between New Haven Harbor and Penfield Reef. The results of these surveys were immediately communicated to the oystermen, permitting more efficient eradication of this pest by private planters. It is planned to expand this service in the future by making surveys every 3 months and issuing the results in bulletin form to be distributed among the interested

Improvements at the Milford station.—During the past fiscal year the Bureau obtained title to property at Milford, pursuant to the provisions of an act of the General Assembly of Connecticut, for the erection of a laboratory building and the establishment of grounds for experimental work on oyster culture. A special allotment of \$35,000 was made by the Public Works Administration for the construction of a two-story brick laboratory. Work will begin early in 1939. Additional funds granted by the Works Progress Administration and Public Works Administration are being used for the construction of a sea wall and pier, filling the grounds, construction of

tidal tanks, and other improvements.

Oyster propagation in North Carolina.—In the South Atlantic region there is great need of the development of oyster cultivation, and of special methods whereby oysters of good marketable size and quality can be grown on the extensive tidal flats. Although generally favorable conditions for oyster growth are found in these areas, the product obtained there is of inferior size and quality because of the overcrowding that results from prolific natural reproduction. One of the chief problems is the development of a practical procedure whereby seed oysters placed on the tidal flats can be protected from crowding and "fouling" of the shells by attachment of oyster spat, barnacles, etc., and grown to marketable size as single individuals of good quality. The three principal lines of investigation conducted

by Dr. H. F. Prytherch during the past year at Beaufort, N. C., in the study of this problem, were to determine (1) the rate and character of growth of seed oysters fastened to panels of cement, wood, and wire placed at different tidal levels, (2) the practicability of using devices of this type for intensive oyster culture, and (3) the possibility of utilizing specially constructed salt marsh ponds for concentrated growing of oysters by controlling setting, and preventing injury to

the shells by the boring sponge.

One hundred and eighty seed oysters were attached to cement panels and studied individually with respect to growth in weight, volume, length, and width in relation to their position above and below lowwater level and their orientation on the panels. The seed used were 1 year old, uniform in size and shape, and showed the following average measurements per oyster: Weight, 15.5 g.; volume, 95 cc.; length, 51 mm. (21/4 in.); and width, 30 mm. (11/4 in.). Three series of panels were placed at the main pier in Beaufort Harbor so that series No. 1 was I foot above mean low-water mark, series No. 2, 1 foot below this level, and series No. 3 on the bottom, or 6 feet below low-water mark. Each series consisted of 60 seed oysters that were cemented in groups of 10 on 6 panels and oriented in the following 6 different positions: Horizontal with left valve down, horizontal with left valve up, vertical with hinge up, vertical with hinge down, sideways with mouth up, and sideways with mouth down. Special care was taken to arrange the panels so that all the oysters in each series had the same environmental conditions.

The principal results of these experiments, briefly summarized, demonstrate that (1) the growth of oysters is most rapid in the tidal zone immediately above low-water level and slowest on the bottom, (2) the greatest increase in weight and size occurs in seed placed in a vertical position with the hinge uppermost, regardless of tidal level, (3) the next best growing position is sideways with the mouth of the oyster upwards, which produces the finest shape and depth of shell, and (4) the procedure of attaching seed to panels, screens, etc., and placing them in the most favorable tidal zone and individual positions, as indicated above, will yield an increase in volume of over 400 percent

during the first year.

The remarkable growth obtained with the best group of oysters of the entire series showed the following increase during the first year: Weight, 360 percent; volume, 410 percent; length, 100 percent; and width, 94 percent. Every oyster of this group attained a good size and shape and exhibited unusual individual growth that ranged from an increase of 190 to 575 percent in weight, and from 210 percent to over 660 percent in volume. The results obtained thus far by the panel method of intensive oyster culture are encouraging as they indicate that a yield of over 5 bushels of marketable oysters, with a value of \$5.00, may be obtained from 1 bushel of seed having an initial cost of 25 cents. This permits an expense of several dollars to cover the operations of placing each bushel of seed on panels and caring for them over a 2-year period. Studies are being continued to perfect an inexpensive type of panel that can be used indefinitely, and to improve the temporary coating that was applied to the shells of the oysters to protect them from attachment of spat, barnacles, boring sponge, etc.

Construction of a series of tidal ponds in the salt marshes has been completed with the aid of W. P. A. labor. Here principles of oyster culture similar to those described above are being tested on a small commercial scale. Several hundred bushels of seed oysters have been planted in the ponds and ditches, where, by control of water levels and tidal currents, it may be possible to produce oysters of good marketable size under protected conditions. This work may have important practical applications in demonstrating how the extensive salt marshes in the South Atlantic region may be converted into oyster-producing areas.

Ouster destruction by starfish in South Atlantic waters.—In the coastal waters of North and South Carolina destruction of oysters and other shellfish by starfish occurs to a limited extent in the more saline waters of sounds and bays adjacent to inlets. At the Beaufort Laboratory studies of the oyster-consuming ability of this pest were conducted over a period of 1 year by Dr. Prytherch. During the first 6 months (January-June) the 10 starfish in the experimental tanks devoured over 1.750 oysters ranging in age from 1 to 3 years. The number of oysters eaten per month over this period ranged from 183 to 456 and was greatest during March and least during June, when the starfish were undergoing the processes of gonad development and spawning.

After July first only large oysters, 3 and 4 years old, were kept with the starfish and during the following 6 months a total of 470 were eaten, the number per month increasing rapidly with the lowering of water temperature. The starfish were frequently observed to leave a partly consumed oyster and almost immediately begin an attack on another specimen, especially after they had been well fed for several weeks. Records of oysters attached to kymographs show that starfish are able to open large specimens in 3 or 4 hours. Analyses are being made of the secretions of starfish stomachs, as they are

supposed to be an effective agent in opening shellfish.

Establishment of experimental farms in South Carolina.—Early in November the Bureau, in cooperation with the South Carolina State Board of Fisheries and the Works Progress Administration, initiated a program for rehabilitating and developing the oyster resources of the State through the establishment of a series of small experimental oyster farms. The primary purpose of this undertaking is to enable tide-water residents in the lower income brackets to obtain their subsistence, in whole or in part, by leasing and cultivating small plots of from 2 to 10 acres of oysters. The program differs from all previous experiments in presupposing that capital requirements will be at a minimum, and that primary materials, equipment, and supplies may be obtained or produced by the labor of the oyster farmer himself.

As early as 1890, interested persons were instrumental in having a survey of State oyster bottoms made by the Bureau of Fisheries, but only within the last few years have leasing laws permitted or encouraged extensive private holdings. A considerable acreage is now so held, but full development of the bottom cannot be accomplished until three major problems are solved.

The first requires development of an inexpensive method for obtaining single seed oysters in place of the massed clusters occuring naturally. This is essential to production of high quality oysters.

In the second place, variations in local water conditions must be understood so that advantage may be taken of those areas where growth and fattening occur most readily. On account of the long spawning season resulting from high water temperature, fattening occurs very late in the season. Southern growers are thus placed at a disadvantage in supplying fat oysters early in the season when the market is usually most favorable. Finally, methods must be devised for using suitable bottom below low-water mark. Under natural conditions, oyster spat attach themselves only between high and low water marks, with consequent restriction not only in the areas available for cultivation, but also in the number of hours the oyster may remain open for feeding.

In view of the importance of these and related problems to the Southern oyster industry, on November 1 the Bureau began an examination of available tidal streams in Beaufort County, S. C., with the view of selecting several areas suitable for small experimental oyster farms of several acres each. This work, in cooperation with the South Carolina State Board of Fisheries, was carried out by R. O. Smith, and several localities were marked for experimentation.

During 1939, various types of bottom will be tested to determine the most suitable treatment for seed and market oysters, and experiments will be carried out to find practical methods of seed col-

lection on a small commercial scale.

Oyster investigations on the Gulf coast.—The oyster industry of the Gulf coast in general has for several years been in a relatively unsatisfactory condition, owing in part to the fact that it depends largely upon natural oyster beds which have been depleted by predators and by too intensive harvesting. The problems will apparently have to be solved by establishing oyster farms on privately leased or owned grounds and by studying the fundamental biological problems concerned before the industry of the coast can be conducted economi-

cally.

The program of oyster investigations which has been undertaken at the Pensacola (Fla.) Laboratory consists primarily of the following phases: (1) Establishment of an experimental oyster farm on a semicommercial scale to determine rates of growth and fattening, productivity annually per unit of bottom, and costs of production, including a study of natural hazards and predators of the Gulf coast. It is planned to compare the results with those of similar projects conducted by the Bureau in Atlantic waters. (2) Experimental laboratory and field studies of factors influencing the growth and fattening of oysters under conditions characteristic of most oyster-producing areas of the Gulf coast, particularly with reference to fluctuations in salinity.

Pending establishment of the experimental oyster farm, Dr. A. E. Hopkins has been working in close cooperation with the Florida Department of Conservation and the Works Progress Administration in a program of oyster planting and rehabilitation of exhausted natural beds in portions of Pensacola Bay. Observations to date indicate that East Pensacola Bay is very favorable for experimental study. Programs were also organized for the rehabilitation of natural oyster grounds in Apalachicola Bay, St. Andrews Bay, and Choctawhatchee Bay. In addition Dr. Hopkins made a number of trips to Mobile Bay at the request of the Alabama Oyster Com-

mission to advise on immediate problems and assist in forming a

general policy of control of the natural beds.

During the year it has been demonstrated that the location of the Pensacola Laboratory, on Santa Rosa Sound, is most satisfactory for its purposes. The water was almost always clear and the salinity varied from about 20 to about 27 parts per thousand in ordinary weather to as low as 12 to 15 parts per thousand during 2 short periods of extreme spring freshets. The water temperature throughout the year followed closely that of the air, and averaged in midsummer about 74° F., in mid-winter about 60° F. Oysters, fish, and other organisms have thrived well in the laboratory aquarium.

With the assistance of relief funds from the Works Progress Administration and the Public Works Administration a program of development of the station was undertaken at the end of the summer. It is expected that early in 1939 the Pensacola station will be adapted

to any type of fishery research.

Effect of pulp-mill pollution on oysters.—Investigations carried out by the Bureau between 1935 and 1937 at the Yorktown Laboratory have clearly indicated that pollution of the river by pulp-mill wastes has been responsible for the decline of oyster production. During 1938, Dr. Walter A. Chipman, Dr. H. N. Calderwood, R. O. Smith, and Lloyd R. Garriss have attacked the problem of determining what chemical or chemicals present in the pulp-mill effluents are the cause of the altered physiology of oysters. The investigators will later attempt to develop a means of eliminating such harmful substances.

The work has been continued on a cooperative basis with the Virginia Commission of Fisheries, which contributed \$5,000, and with the cooperation of the College of William and Mary which granted the use of the chemical laboratory and office space in the college building at Williamsburg. In addition to the work in Virginia, special phases of the York River pollution problem were investigated in the Washington Laboratory by Dr. Galtsoff, with the assistance of Dorothy B. Hamilton. These were the abnormal shell structure and other pathological conditions found in oysters from the polluted areas of the York River.

In testing the effectiveness of pulp-mill wastes in reducing the amount of water pumped by oysters, it has been observed that only one of the various effluents entering the York River from the pulp and paper mill at West Point has a marked physiological action—that arising from the pulping process. This mill has three main sewer ditches; one draining a sludge deposit, one receiving wastes from the paper mill and causticizing section, and one carrying the wash waters from the diffuser and the digester building and evaporators.

Frequent sampling of the discharges from the sewers has revealed wide and irregular fluctuations in the character and physiological activity of the effluents. However, these effluents have been grouped under three main categories for the purpose of study; crude sulphate soap, foam from the mill sewer outlets, and weak black liquor.

At times considerable quantities of crude sulphate soap find their way into the effluents, being washed in from the ground surrounding the black liquor storage tanks. These soaps have a marked physi-

ological action in reducing the rate at which water is pumped by oysters. Fractionation of crude sulphate soaps has yielded portions both physiologically inactive and physiologically active. Studies are under way for the purpose of isolating, if possible, the single active constituent. A future study will be the determination of the part the physiologically inactive materials may play in the distribution and duration of the potency of the active portions.

Frequently large quantities of foam are observed in ditches leading to the river. Examination of the foam indicates the likelihood of its being a soap rather than a saponin. Further work is planned on the chemical nature and the effect on oysters of this material.

Tests of material entering one of the sewer ditches from an overflow of foam from the weak liquor storage tanks indicate that this material is chiefly a dilute form of the so-called "black liquor" which results from the digestion of the wood chips, with possibly an addi-

tion of a small amount of soap.

Chemical investigations are planned on black liquor samples for the purpose of finding whether any correlation exists between the alkalinity and volatile sulfide content of the various black liquor samples and the variations in effect on oysters exhibited by these samples. Fractionation of the black liquor will be undertaken, and efforts to develop a reliable method for the detection and determination in river waters of constitutents of the black liquor will be continued.

Tests on the physiological effectiveness of pulp-mill effluent have shown that storage of weak black liquor in air brings about a slow loss in potency. It seems that this change is chiefly in oxidation, since agitation in the presence of pure oxygen under pressure rendered the material physiologically inactive, whereas the effluent stored under hydrogen held its potency at a constant figure for periods of from 2 to 3 months.

SPECIAL SURVEYS

Under the direction of Dr. Galtsoff, a study of the sequence of fouling organisms on experimental panels exposed by the United States Navy at Cavite, P. I., and Guantanamo Bay, Cuba, was completed by G. Robert Lunz, Jr., and the report was prepared and submitted to the Navy Department. Preliminary experiments on the nature of

the fouling film were carried out at Langley Field, Va.

At the request of the United States Engineers, Dr. Galtsoff made a survey of oyster bottoms in Onset Bay claimed to be affected by dredging operations in the Cape Cod Canal. Numerous samples of water and oysters were taken for examination. Certain areas were found to be covered with recent deposits of sand and mud and contained large numbers of dead oysters. Since the examinations were made long after the completion of dredging operations in this section, the cause of the mortality of oysters could not be ascertained.

Another survey of similar nature was made in Narragansett Bay at the request of the United States District Engineer in Providence. Fortunately, in this case, the survey was made while the dredging operations were still in progress. Samples of oysters were obtained from 16 stations on both sides of the canal. Examination of oysters

revealed no ill effect from the dredging operations. There was no accumulation of mud on ovster shells or in the shell cavities. The oysters appeared to be healthy and normal. It is planned to continue these surveys in Narragansett Bay as long as the dredging operations

Mortality of shellfish, Myrtle Sound, N. C .- At the request of the North Carolina Department of Conservation and Development, Dr. Prytherch made a survey of an unusual mortality of clams and oysters in the waters of Myrtle and Masonboro Sounds. found that hydrographical and biological conditions in these sounds had changed considerably since the construction of the Intracoastal Waterway and had proved to be detrimental to the growth and propagation of shellfish in this coastal region. The most important modification is the connection of the Cape Fear River with the southwest end of Myrtle Sound by means of a canal, approximately 100 yards wide, known as Snows Cut. This canal, being open at all times, permits a considerable quantity of fresh water, or water of low salinity, to flow into Myrtle and Masonboro Sounds. During flood stages of the river especially large quantities of fresh water, heavily laden with mud, pass continuously through these sounds for extended periods and enter the ocean at Masonboro Inlet. During the early part of August the unusual floods occurring in the Cape Fear River Basin produced such extreme freshening of the water in these sounds as to cause destruction of the natural supply of clams and oysters.

The value of the oyster crop of this region, which prior to 1932 was approximately \$3,000 annually, decreased to less than \$400 in 1936 and 1937. It is evident that the clam and oyster resources of this section, which have a combined value of \$15,000 annually and serve as a means of food and livelihood for a large number of local people, should be restored after some satisfactory flood control devices have been installed to control the flow of fresh water from the Cape Fear River.

AQUICULTURAL INVESTIGATIONS

Dr. H. S. Davis, in charge

It has long been recognized that our inland waters constitute one of the great natural resources of the country which, like other resources, are now suffering serious depletion. Industrial and agricultural development have so changed the nature of many waters that they are no longer suited to fish, while the majority of those that are still capable of supporting game and food fishes are badly overfished. These conditions can best be corrected by wise management combined with artificial propagation.

The work of the aquicultural investigations has developed along three principal lines. One deals primarily with field problems and the provision of much-needed information on the best means of obtaining the maximum production of game and food fishes consistent with environmental conditions. A second line of investigation is concerned with problems relating to the artificial propagation and rearing of fish, while the third deals with fish parasites and diseases, and

their control.

TROUT

It is the purpose of the investigations on trout waters to obtain definite information on the annual drain to which the trout population is subjected by anglers, and the value of artificial stocking in maintaining a stable fish population. Attention is also being given to the correlation between normal production and the available food supply and other factors which must be given consideration in de-

veloping management policies.

Test streams.—The scientific work at the Pittsford (Vt.) station, under the direction of R. F. Lord, was again chiefly concerned with studies on test waters. Waters set aside for this purpose include three streams and one lake operated in cooperation with the State Fish and Game Service. On one of these streams, Furnace Brook, a State game warden was stationed each week end to examine anglers' catches for marked fish and to obtain data on the lengths and weights of all trout taken from the stream.

On both Furnace Brook and the South Branch of Middlebury River the total catch for the season was considerably less than in previous years. Unfavorable conditions during the winter of 1937-38, when heavy winter rains raised the streams to flood stage with much damage from floating ice, are believed to have been the cause of the exceptionally poor stream fishing throughout the State.

The superiority of rainbow over brook trout in contending with adverse conditions is again brought out clearly in the results from Furnace Brook. As pointed out in previous reports, no rainbows have been planted in Furnace Brook for years, while the stream is heavily stocked each year with fingerling brook trout and, for several years past, with yearling brook trout as well. Nevertheless, the catch of brook trout has shown a gradual decrease each year while the decrease in the catch of rainbows has been comparatively slight, with the result that the proportion of rainbows rose from 34 percent in 1935 to 38 percent in 1937. In 1938 this trend was accelerated; rainbows increased to 62 percent, while brook trout provided only 38 percent of the catch. Furthermore, the average catch of rainbow trout per angler, which had remained constant during the preceding years at 24, in 1938 jumped to 3.7.

The returns from 5,200 yearling brook trout planted in Furnace Brook in the fall of 1937 were very disappointing, only one percent of these fish being reported by anglers. The 1937 record of only 12 percent recovery was thought low but it remained for adverse wintering conditions to show how a fall plant of yearlings could be

a total loss.

Fish population studies were made on the three test streams in cooperation with the United States Forest Service. The procedure was to block off a section of the stream with seines at the upper and lower ends. These were weighted with stones so as to prevent any fish entering or leaving the section. A dam of burlap sacks filled with sand was then constructed across the upper end of the section so as to divert the water into another channel. Any pools that could not be drained were pumped dry so that every fish present could be captured. The average number of trout per acre in three sections of Furnace Brook was 835, with a total weight of 35 pounds, 11

ounces. Only 15 percent of the trout were of legal size, 10 percent

of these being brook trout.

In the South Branch of the Middlebury River the average number of fish (based on two sections) was 1,650 brook trout per acre, with a total weight of 54 pounds, 10 ounces. As in Furnace Brook, 15 percent of these fish were of legal size. There were no rainbow in Middlebury River and fish other than trout were too few to be of any significance.

The West Branch of the White River was found to have a much smaller population of trout. Three sections of this stream yielded an average of 376 trout, weighing 14 pounds, 10 ounces, per acre. This stream also supports considerable numbers of sculpin, dace, and suckers which, when added to the trout, give a total of 20 pounds,

14 ounces of fish per acre.

Studies on St. Marys River.—Monthly collections of bottom and chemical samples on the St. Marys River. Virginia, were continued during the spring, summer, and fall of 1938, to determine the effect of different current velocities on abundance of bottom animals in riffle areas. Samples collected during the past 2 years have been very uniform, with an average weight of slightly over one gram per square foot. In contrast with streams in the Southern Appalachians, there were fewer organisms in summer than at other seasons.

It is evident that stocking St. Marys River with fingerling trout has not produced worthwhile results and that rainbow trout dis-

appear before they reach legal size.

Investigations in Pisgah National Forest.—The experimental fish-management program in Pisgah National Forest, North Carolina, was conducted for the second year in cooperation with the United States Forest Service. The project sustained an irreparable loss on January 4, 1939, in the death of Wm. M. Keil, who had been in charge of the project for the Forest Service since its inception. The work will be continued by Thomas K. Chamberlain, who has been conducting the biological studies for the past 2 years.

During the late summer and early fall of 1937 the streams of the Wildlife Management areas of the forests were stocked for the first time under the new program. After determining the carrying capacity of these streams, brook, brown, and rainbow trout were planted by the most approved methods. In order to develop and maintain satisfactory fishing it had been decided to plant larger fish and to develop some system of rotating the open season on the several watersheds in order that each stream might have a period of rest after being fished and restocked. Several of the streams were opened to a limited amount of fishing during the summer of 1938.

The danger of overstocking when streams are not rich in food has been demonstrated in several small streams of this area. In one instance a planting of brook trout averaging over 6 inches long was made in the fall. These fish remained in excellent condition through the winter but in early spring they began to decline, and, in late summer, 10 months after planting, their average weight was less than

when first put into the stream.

Stream studies were carried out by Mr. Chamberlain to determine the rate of stocking for the various waters. Quantitative collections of food organisms were made from 977 square feet of trout-stream bottom in the Pisgah Forest alone. Observations were also made on the trout present and on stream conditions in general. While streams in the Pisgah Forest received most attention, a start was made in studying the main streams of the Cherokee, Chattahoochee, and Nantahala National Forests, where food conditions appear to be much

the same as in streams of the Pisgah Forest.

In general, the forest streams in this region may be classified as medium to poor. Most of them still suffer from excess of sediment, due largely to road construction and in some parts of the Pisgah Forest to overbrowsing by deer. However, conditions appear to be improving and were it not for uncertainties in future road construction the outlook would be distinctly encouraging.

Feeding experiments.—Extensive feeding experiments with fingerling, yearling, and adult trout were carried on at the Leetown station, supplemented by experiments with fingerlings at the Pittsford station. These experiments were designed primarily to determine the effect on growth, mortality, and egg production of dry meals fed at

different levels and in different combinations.

In general, it was found that fresh meat is more efficiently converted into fish flesh than dry feeds but, owing to the lower cost of the latter, it is more economical to incorporate a considerable percentage of these products into the diet. Using a mixture of the better dry meals, best results were obtained when the meals were fed at a level of 40-50 percent.

One of the most striking results was the marked increase in growth following the addition of 3 percent cod-liver oil to a diet composed of sheep-liver and whitefish meal. Overfeeding failed to produce high

mortality or any evident pathological effects.

Experiments with brood fish showed considerable variation in the hatchability of eggs from fish on different diets, amounting in some cases to over 50 percent. Overfed lots produced twice the number of eggs per female obtained from underfed fish on the same diet but the percentage of eyed eggs was more than 10 percent greater in the underfed lot.

Cooperative nutrition studies.—Studies on the nutrition of trout were continued under the cooperative agreement between the Bureau of Fisheries, the New York Conservation Department, and Cornell University. These investigations are carried out at the Laboratory of Animal Nutrition of the New York State College of Agriculture at Ithaca, N. Y., and at the Cortland (N. Y.) Hatchery of the Bureau of Fisheries. The staff conducting these studies consists of Dr. C. M. McCay, A. V. Tunison, A. M. Phillips, E. O. Rodgers, and C. R. Mitchell. Inasmuch as detailed reports of the progress of these investigations are published annually by the New York Conservation Department, only a summary of the results is included in this report.

The study of the growth rates of four species of trout during a period of more than 5 years (March 10, 1933-September 16, 1938) has been terminated. The trout used were lake, brown, rainbow, and brook. In this study the best survivors were the lake trout. These continued to grow, but at a very slow rate, until discarded. The brook trout were the poorest from the point of view of survival. The growth curves of these four species ran parallel throughout.

During the past few years many new vitamin concentrates have been made available, opening new possibilities for determining the needs of animals for vitamins. During the past year new studies were made employing synthetic diets supplemented with liberal supplies of vitamin concentrates. All recognized vitamins were included in these supplements but this mixture could not replace the factor H of fresh meat. Present knowledge about the part any of the vitamins play in the growth and well-being of trout is extremely limited.

New attempts were made to prepare concentrates of factor H from liver but with little success. Ten percent of fresh liver added to a synthetic diet seems to satisfy the requirements of trout for all vitamins. In accordance with our earlier studies it seems that liver

retains part of its factor H when dried in vacuo.

Studies with meats and fish preserved in various ways have been continued. Some success has resulted from feeding meat such as spleen preserved with salt. No injurious effects have resulted from

feeding high levels of salt to brook trout.

Since ordinary dry feedstuffs contain about 10 percent of moisture, an attempt has been made to dehydrate fresh meat by mixing it with very dry feed mixtures. By starting with a very dry diet sufficient fresh meat can be added to bring the mixture to its normal content of about 10 percent. Preliminary tests with this method indicate

that part at least of the factor H is preserved.

Intermountain Region.—Fish management work in the Intermountain Region in cooperation with the United States Forest Service and the fish and game commissions of the several States, which had been discontinued for several years, was resumed with the appointment of Dr. Stillman Wright as regional biologist. Dr. Wright established his headquarters at Logan, Utah, on June 9, where the State Agricultural College has very generously provided adequate laboratory facilities for him and his assistants. Since entering upon his duties Dr. Wright has spent considerable time familiarizing himself with conditions in this region, in the course of which he has traveled approximately 17,400 miles by automobile.

Trout are the principal game fishes of this region in which, as elsewhere, the number of anglers and consequent intensity of fishing is increasing very rapidly. Failure of the fisheries to maintain themselves under the heavy demands of the public is evident in the streams, particularly those near centers of population. In lakes and reservoirs excessive removal of trout is usually followed by a great increase in the less-desirable species. Factors other than overfishing are, however, involved in the general decline of the fisheries in this region. Silting, resulting from overgrazing and accelerated erosion, makes streams less suitable for trout. In many streams hydroelectric and irrigation projects interfere with normal migrations, while fluctuations of the water level in reservoired lakes interferes with normal spawning and may have other detrimental effects. Because of the variety and critical nature of the many problems involved, it is evident that for some time investigations in this region must be directed toward the formulation of management plans for waters showing possibilities of immediate improvement of fisheries resources.

During the past summer special attention was given to Fish Lake, Utah, which formerly supported a highly productive fishery for rainbow, mackinaw, and brook trout. Some years ago the Utah club was introduced and has since become extremely abundant. As the

chub increased in numbers the brook trout decreased in abundance and average size until it is now a negligible item in the catch. There is reason to believe that the rainbow and mackinaw are also on the decline.

The results of earlier studies combined with those of last summer have made it possible to formulate a program of management which gives promise of improvement in the fishery. The following recommendations have been made to the State Department of Fish and Game: (1) That a program of eradication of the Utah chub be instituted, (2) that a forage fish especially suited to the needs of the mackinaw trout be introduced, (3) that plantings of rainbow and mackinaw trout be continued, (4) that the present catch limit be drastically reduced and that attempts be made to develop other lakes for fishing, so as to decrease the fishing intensity in Fish Lake.

In the search for a forage fish to meet the needs of the mackinaw trout, attention was directed to Bear Lake, Utah and Idaho, which has three species of Coregonidae found nowhere else. One of these, the Bonneville cisco (*Leucichthys gemmifer* Snyder), may prove to be a valuable forage fish, and a study of its life history has been begun. A more detailed study of Bear Lake is planned for 1939. At the present time the trout fishery in this lake is in a deplorable condition and a number of factors conspire against improvement.

California trout investigations.—The work of this research unit has remained under the direction of Dr. P. R. Needham, with head-quarters at the Natural History Museum of Stanford University. Dr. Osgood R. Smith was appointed to the staff in the position of Assistant Aquatic Biologist. The cooperative agreement that had been in effect since 1932 with the California Division of Fish and Game was abrogated by mutual consent on July 1, 1938.

Cooperation with the United States Forest Service was continued, but lack of funds limited the extent of the work. Angling catch records were taken for a second season on Fish Lake, in the Umpqua National Forest, Oregon. Lack of funds caused abandonment in August of the survey of the North Fork of the Umpqua River and its tributaries when only partially completed. The survey of lakes in the Willamette National Forest was completed and a report covering the entire three years' work and containing stocking policies for all lakes suitable to fish life is now being prepared. A survey of lakes in the Columbia National Forest in Washington was begun, and it is planned to continue the work next season if funds are available.

Complete catch records were secured for a second season on Squaw Creek in the Shasta National Forest, Calif., and a report is being

prepared that will cover the 2 seasons' activities.

Loss of Mexican trout.—The flood of March 2, 1938, in southern California completely destroyed the Forest Home State Fish Hatchery, near Redlands, and with it both the adults and eggs of Salmo nelsoni brought to California from Baja California, Mexico, in the spring of 1937. An attempt will be made to secure another lot of these fish for breeding purposes.

Convict Creek experimental stream.—Experiments to determine the survival rates of hatchery-reared trout planted under controlled conditions were continued. Fifteen plants of marked rainbow and brown trout were made in the experimental stream, 13 of which were successful. The survival from plants of advanced fry and eyed eggs gave further confirmation of last year's results. From a plant of 3,000 eyed cutthroat eggs, 465 fish, or 15.5 percent, survived after 51 days. A slightly higher survival of 21.7 percent was obtained from a plant of 2,000 unfed fry. These results were obtained under light predation, and survivals are slightly higher than any obtained last year. In contrast, a plant of 1,000 unfed fry showed a survival of only 1.4 percent under heavy predation, 64 wild trout being taken from this section at the end of the experiment.

Brown trout fingerlings, planted at the usual size at which they are planted from State hatcheries, showed surprisingly high survivals after 3 months. For instance, in one section a survival of 76.4 percent was obtained after 94 days, in spite of the fact that 117 wild trout were also present in the section. These fish were planted at a length of 1.5 inches and averaged 3.2 inches at the end of the experiment. By way of comparison, wild brown trout of the same age, netted from Convict Creek, showed a survival of over 89 percent

after 97 days under heavier predation.

Small rainbow trout, averaging 1.7 inches in length, planted in two experimental sections, showed survival rates of 75.6 and 83.1 percent, respectively, after 95 days. These fish were planted without removing wild fish and no effort was made to protect them from

other predators.

One of the most surprising results has been the large numbers of naturally spawned fish that are found in the experimental sections at the end of the season. This year a total of 1,123 wild brown, rainbow, and eastern brook trout were removed from the 15 experimental

sections, an average of 74 wild fish per section.

Some much-needed improvements were made during the past year, including the construction of a small cabin for living quarters, and a few changes in the experimental section. Floodwaters in late June interfered with the experiments to some extent. Late in the fall a flood diversion ditch was constructed which will make it possible to divert at least a portion of high water out of the main channel and

around the experimental area.

Shasta Dam survey.—A party of four biologists, employed by the United States Reclamation Service, has been engaged in an investigation of the salmon-salvage problems resulting from the construction of the Shasta Dam on the Sacramento River. This work is under the immediate direction of Dr. Smith. During the summer most of the spawning areas above the dam were located and measured to determine the extent of such areas that will be destroyed upon completion of the dam. Streams below the dam were also examined for suitable spawning areas.

On the basis of counts made of salmon passing over the fish ladder at the irrigation dam at Redding, it is estimated that there are approximately 20,000 salmon in the fall run alone, which would indicate a potential deposition of over 70 million eggs in the area that

will be cut off by the dam.

Dam debris survey.—Late in June a crew of four men was employed by the United States Engineer Corps to make a study, under the direction of Dr. Smith, of the fisheries problems arising from the

construction of three dams on the American and Yuba Rivers in California. Data were gathered during the summer by standard stream survey methods and, in addition, two men were employed to count salmon ascending the rivers. The counts were incomplete and do not include a reputedly sizeable steelhead trout run. They do, however, indicate that it will be mainly sport fishing and not the commercial salmon fishery that will be affected by the dams and mining debris.

Survey of Pyramid Lake, Nevada .- A survey of Pyramid Lake and its fisheries problems was made between March 7 and June 8 at the request of the Indian Service. Francis H. Sumner was stationed at the lake to gather biological, physical, chemical, and historical data on the lake and on Truckee River, which formerly was the spawning ground of great runs of cutthroat trout. With the aid of Indian wardens a record was kept of the commercial catch made by the Indians, which has declined greatly in recent years. Length-frequency and age studies show that the run is at present made up almost entirely of old fish, averaging 34 to 35 inches long, and that the younger age groups are not represented. This age and frequency is the reverse of that usually found in an over-exploited fishery. It appears that the run was but a remnant of a race that has practically ceased to reproduce, from lack of spawning facilities. Overfishing by the Indians has probably been a factor in depleting the run, but it is evident that the diversion of the Truckee River water has been the major cause. It is considered doubtful that rehabilitation could be effected by any means.

BASS

Studies on streams in Virginia and West Virginia.—Field work on bass streams, begun in 1936, was continued at the Leetown (W. Va.)

station by E. W. Surber and George E. Klak.

These studies are designed primarily to determine the extent and efficiency of natural propagation of bass and the effect of intensive fishing on the bass population. They show that, even in heavily fished waters, there is little danger of the bass population being seriously depleted if adequate spawning facilities are available. Intensive fishing frequently results in excessive numbers of small bass, with consequent reduction in the abundance of forage fishes. It is apparent that the remedy is to build up the food supply and that stocking with young will only tend to intensify the unbalanced condition.

Monthly series of bottom samples were collected from the experimental sections of four streams, namely, the Cacapon River, South Branch of the Potomac River, North Fork of the Shenandoah River, and the Shenandoah River. This series of samples duplicates those taken in previous years. Special attention was given to measurements of current velocities at all sampling stations. Laboratory work on the bottom samples has been completed, but the data have not yet been analyzed.

Studies of the extent of natural propagation were continued in these four rivers. In contrast with previous years, interruption of the spawning season by cold weather and muddy waters brought about a second spawning early in June. In previous seasons spawning was completed by the 1st of June. The number of bass nests

per mile was 70.7 in the Cacapon River, 81 in the South Branch of the Potomac, 24 in the North Fork of the Shenandoah, and 11 in the Shenandoah River proper. It is believed that in ordinary years an excessive number of fry are produced in the first two rivers. During the past year, however, high and muddy waters destroyed the fry as they rose from the nests and there was a decided scarcity of fingerling bass throughout the season. Routine monthly collections of fishes showed that a reduction in the numbers of fingerling bass is accompanied by an increase in the forage fish population. After July, collections of bass fingerlings for study became increasingly difficult or impossible because of their scarcity.

As in previous years, conditions in each stream were found to differ in many respects and each would require different treatment to bring about improvement in fishing. Minnow surveys were made in 11 experimental sections in an attempt to determine whether reasonably reliable data could be collected on the size of the forage

fish populations in the four rivers concerned.

Investigations in Florida waters.—In recognition of the need for extensive studies on black bass and other fresh-water game fish in Southern waters, and their propagation by artificial means, headquarters for this work was established at the hatchery recently acquired by the Bureau at Welaka, Fla. This station, located on the banks of the St. Johns River, is admirably adapted to experimental work. There are a large number of ponds, ranging from seven-eighths to 2 acres in area, which have recently been remodeled to make them more suitable for experimental work. New buildings have been constructed which will provide adequate laboratory, office, and living facilities for biologists working at the station. Opposite the station, on the west side of the St. Johns River, is the Ocala National Forest, which contains several streams and a large number of lakes rich in aquatic life. Through a cooperative agreement with the United States Forest Service and the Florida State Commission of Game and Freshwater Fish, eventual management and control of all lakes in this area is contemplated.

Investigations in this area, both at the Welaka station and in the field, are being conducted under the direction of O. Lloyd Meehean. Mr. Meehean began his work on the waters of the Ocala Forest in

April 1938, and later moved his headquarters to Welaka.

A survey of the principal lakes in the Ocala Forest was carried on during the summer of 1938 to provide information to be used in developing a management program for these lakes. The survey included plane-table mapping of the lakes by a crew of C. C. C. enrollees, complete soundings of each lake, and the determination of the species of fish present and their relative abundance. From this survey maps have been prepared showing bottom contours, the location, kind, and extent of weed beds, and other pertinent information.

Based on this survey, a stocking program has been worked out for 19 lakes that are fully controlled by the Forest Service. Most of the lakes are to be stocked with bass and sunfish, but several which appear ideally suited to crappie have been reserved for this species.

To determine the fishing demand to be expected on lakes of the forest, checking stations were set up on two of those most accessible

to anglers. At these stations a complete census was started on May 21, the opening day of the fishing season, and will continue until the close of the season on March 21, 1939. Bottom samples, two types of plankton samples, and chemical data are also being collected on these lakes.

In addition to the lakes under management, seven ponds have been set aside for experimental work. This number will be increased as needed. These ponds will be utilized for stocking experiments and study of methods to increase the food supply of game fish in these waters, as the basis for improvement in the management

program.

In the Choctawhatchee National Forest there are a number of streams that are inhabited by largemouth bass at the lower end where they enter coastal bays, but which contain no game fish higher up. These streams are peculiar in that the temperature of the water is about the same throughout the year. A study is being made of the physical conditions and life in these streams to determine how they can best be utilized.

Experiments relating to hatchery problems will be started early in 1939 when the remodeled ponds at the Welaka station will be

ready for use.

PARASITES AND DISEASES OF FISH

Facilities at Seattle, Wash., for the study of problems relating to fish diseases were greatly increased during the past year. These studies are under the direction of Dr. F. F. Fish. Two experimental laboratories are now available, each operated for a slightly different purpose. One is an enlargement of the field laboratory constructed at the Quilcene (Wash.) hatchery in 1937. The original temporary structure has been replaced by a permanent building constructed by the Division of Fish Culture according to plans provided by Dr. Fish. As this laboratory was planned primarily for testing scientific discoveries under controlled field conditions, it is not suited to

all types of experimental work.

A second experimental hatchery has been provided, through the generous cooperation of the University of Washington, in the basement of one of the university buildings. This laboratory is supplied with chlorinated water, which is subsequently dechlorinated by passage through an activated carbon filter, thus assuring a disease-free source of water. The laboratory contains 24 small troughs which have proved highly satisfactory for this type of research. The main water supply to the troughs is controlled by a manually operated master valve and mixing chamber which permits the maintenance of any desired temperature in the troughs. When finances permit, the water supply of 10 of the experimental troughs will be additionally controlled by automatic thermostatic valves.

Much of the long-term scientific program of the Seattle Laboratory had to be considerably modified during 1938 because of the lack of suitable facilities during the construction period. As long as the original Quilcene Laboratory could be used, a series of toxicity studies was maintained to determine the maximum nontoxic concentration of disinfectants which fish could withstand for various

lengths of time. The value of these concentrations in preventing certain diseases was then tested at producing hatcheries by means

of routine 1-hour applications at weekly intervals.

During the course of the experiments, which extended over a period of 3 months, a serious outbreak of the Western type of gill disease occurred at the Birdsview (Wash.) Hatchery, and a mild outbreak at the Quinault hatchery. Prolonged treatments with malachite green, potassium permanganate, and chlorazene failed to exert any beneficial effect in preventing the disease. A considerable drop in the mortality followed treatments with copper sulphate and boric acid, but further experiments with both chemicals will be necessary before any conclusions concerning the prophylactic or therapeutic values of these disinfectants are justified.

During 1938 a new technique was developed for treating fish in relatively large volumes of water, such as are found in circular pools and in raceways. In this method the water supply to the pond is shut off and the amount of predissolved disinfectant necessary to attain the desired concentration is added. The water is kept mixed and aerated during the treatment by means of a

centrifugal pump.

After completion of the new laboratory at Quilcene, a series of controlled infection experiments with the protozoan parasite Cyclochaeta were initiated. The purpose of the experiments was not only to trace the development of the disease under controlled conditions but primarily to determine the relationship between daily losses and the actual degree of infection present. The results indicate that while daily losses are by no means an accurate index of the degree of parasitism, and are unsuitable for experimental purposes, they are sufficiently accurate to serve all practical purposes.

Pathological studies on *Henneguya salminicola*, a myxosporidian parasite in the body musculature of several species of Pacific salmon, and similar studies on *Myxobolus inornatus* n. sp., a myxosporidian found in the body musculature of the black bass, were completed and

the results prepared for publication.

At the Leetown station E. W. Surber completed a study of a peritrichous ciliate of the genus Scyphidia, which occurred in large numbers on the gills and bodies of black bass at this station. This parasite was discovered on a lot of largemouth fingerlings which suddenly stopped feeding. No attempt was made to control the infection and within a few days the fish suffered a sudden and almost complete mortality. Although a few Dactylogyrus and Cyclochaeta were also found on the fish the Scyphidia are believed to be the principal cause of the mortality. This is borne out by the fact that the same pond contained numbers of golden shiners which were more heavily infected with Dactylogyrus than the bass, yet suffered only a slight mortality. No Scyphidia, however, could be found upon these fish.

Dr. Davis continued his studies on a suctorian parasite of the smallmouth black bass which has been the cause of considerable mortality at Leetown among bass of all ages. This parasite is evidently widely distributed, since it has been found at several hatcheries in New York, New Jersey, and Maryland.

The "Disease Service" continued to function during the past year, about the same number of specimens being received for diagnosis as

in previous years. One very gratifying feature is that some of the hatcheries have ceased to be steady clients of the service, which would indicate that the common diseases are now under better control.

Dr. Davis spent some time at the York Pond (N. H.) station in connection with an outbreak of furunculosis. In an effort to eradicate the disease the trout were either removed or destroyed and the ponds and hatchery disinfected with chlorine and hydrated lime. Owing to the nature and extent of the ponds this was a very difficult task but it is believed that it was accomplished successfully.

INVESTIGATIONS IN INTERIOR WATERS

DR. M. M. Ellis, in charge

POLLUTION STUDIES

Headquarters for the pollution studies have continued at Columbia, Mo., where the University of Missouri has courteously provided laboratory space and facilities. A subsidiary laboratory at Fort Worth, Tex., has also been maintained. The various phases of the pollution investigations are so organized that they contribute to the central purpose of determining the suitability of particular waters both in the stream and in the hatchery for different types of fishes, the detrimental action of many substances which enter streams or water supplies either naturally or through pollution, and reliable means for measuring the condition of the fish themselves. In this work cumulative effects and impairment of vital functions are receiving more attention than the immediate lethality, as the former are both more insidious and far reaching than the latter.

Three major lines of investigation are in progress at the Columbia

field unit and the Fort Worth Laboratory.

Analytical studies.—Waters, muds, and aquatic organisms collected in the field are sent to the central laboratory for detailed analysis. Determination of these samples is carried out by Dr. B. A. Westfall and assistants. In addition to the materials collected in the course of field work conducted by the staff, a large number of samples

are sent in for analysis by the various State agencies.

Bioassays.—The specific effects of materials found in waters, muds, and pollutants, on living fish and other aquatic animals, are determined by the bioassay method. The bioassays of pollutants sent to the Columbia unit by State authorities and other sources have grown to be an important activity of the laboratory, with 50 to 200 such assays constantly in progress. Equipment and procedures have been so standardized that it is possible to assign a considerable portion of this work to analytical assistants who carry on these tests as routine tasks.

Physiological investigations.—The underlying causes for the actions of the various substances found in natural waters and pollutants on living fish are sought through studies of the physiology of fish. This phase of the work is under the direct supervision of Dr. Ellis and is conducted both in the Columbia Laboratories and at Fort Worth. A major field of physiological investigation during the year was a study of the effects of various components of larvacides and herbicides on fresh-water fishes and associated aquatic food

organisms. As the biochemical and physiological tests are quite exacting, each fish is maintained and studied as a separate patient, frequently for a period of several months. More than 200 such fish are under observation at Columbia, and upwards of 500 catfish are being studied as part of this investigation at Fort Worth. studies have progressed to the point where it is possible to conclude that there is impairment of the growth and nutrition of fishes in waters treated with even small quantities of arsenicals and several other materials commonly used as mosquito larvacides. A separate report on this subject will be prepared early in 1939.

During the latter part of the year physiological studies were begun to determine the effects of several substances dangerous to fish life which were found in natural waters in the West in the course of the summer's field investigations. These studies are being carried out in

both the Columbia and Fort Worth Laboratories.

Summer field surveys.—During the summer of 1938 intensive studies of stream pollution were made throughout the greater part of Western United States, and many new data were collected on the nature and effects of polluted waters. Observations were made in the States of Texas, Arizona, Nevada, California, New Mexico, Oregon, Washington, Idaho, Wyoming, Montana, Minnesota, North Dakota, and Nebraska. About 5,000 analyses were made in the field and additional material was returned to the laboratory at Columbia, Mo., for further analysis.

After leaving Columbia early in the summer, Dr. Ellis and field party proceeded to the Fort Worth (Tex.) Laboratory where particular attention was given to the catfish investigations in progress there. From Fort Worth the party proceeded to Uvalde, Tex., where a study of water conditions indicated the source of at least one of the difficulties hampering pond operations, not only at Uvalde but also throughout the Southwest. While in Texas, the party had an opportunity to make direct observations on the silt and salt loads

of floodwaters, obtaining valuable data.
Studies of impounded waters continued at Elephant Butte Reservoir in cooperation with the United States Reclamation Service and the National Research Council, and at Lake Mead in cooperation with the same agencies and the National Park Service. At Elephant Butte opportunity was afforded to use a new piece of apparatus recently developed in the Columbia Laboratories by means of which direct determinations of silt, turbidity, water temperature, and light transmission were possible inch by inch throughout the entire depth of the lake. This new apparatus gave valuable detailed data confirming previous observations made by less accurate methods. plication of various new methods and pieces of apparatus to surveys of these western impounded waters is proving very profitable and is providing a wealth of new information on water problems which has not been available previously. A manuscript on Lake Mead is planned, comparable to the one on Elephant Butte now nearing completion.

After completing the work at Lake Mead the party proceeded to the geyser fields and the Hot Creek region in California where a large series of observations were made. At Gold Beach, Oreg., work carried on during the previous summer on the Rogue River mining

problems was checked and extended.

In the Mount Rainier section studies of glacier waters were continued. In addition to making observations on the three major glacier fields, Nisqually, Puyallup, and Edmonds Glaciers, the party studied a large number of streams receiving glacier waters. After completing the work in the vicinity of Mount Rainier the field party moved over into the Columbia drainage and made extensive observations on the Columbia River and its tributaries above and below Rock Island Dam. These data form parts of series collected in previous years which it is believed will ultimately be of service in answering some of the questions concerning the establishment of new salmon runs in these streams.

Dr. Westfall, who carried on laboratory experiments at Columbia during the months of June and July, and looked after the field material as sent in, joined Dr. Ellis' party at Lake Mead the second week in August. Enroute to Lake Mead Dr. Westfall, with field truck and equipment, covered various streams in northern New Mexico and Arizona. Dr. Westfall remained with the main party from Lake Mead to Glacier Park, then proceeded east through Montana and North Dakota to check water conditions in the Fort Peck Dam area, the headwaters of the Missouri, and at Jamestown and Valley City, N. Dak., where proposed hatcheries are being considered. From North Dakota he proceeded east through Minnesota and made an investigation of the pollution situation on the Rainy River.

The main field party proceeded south from Glacier Park through the lead district of north Idaho and the copper district of Montana to check observations at regular stations, thence through Yellowstone Park and Wyoming, giving particular attention to streams from geyser fields or from heavily mineralized districts. Reaching the southern Wyoming line, the party was again split so that two sets of streams, one across Colorado and one across Nebraska, were sampled by the returning parties enroute to the Columbia (Mo.)

station.

Because of improved apparatus and new methods used, summer field studies were much more detailed during 1938 than heretofore. Special apparatus was carried, by means of which physiological studies of the fish were made in the field. This innovation proved very successful and yielded not only valuable but also surprising data in many cases. It is well known that moving fish or other animals from their natural habitat, even under the most rigid precautions, frequently results in physiological changes so that the examination of these live animals in the laboratory often fails to give a true picture of their conditions in the field. With the special physiological and biochemical apparatus carried the physiological observations and tests were made immediately at the stream in which the fish were living. It is believed that these data will supply a much truer picture of the physiology of our fresh water fishes than has hitherto been available.

Summary of progress during 1938.—Studies of stream pollution during the past year have demonstrated more clearly than ever before the fact that high dilutions of many substances, introduced by man into streams, lakes, and reservoirs, or entering these waters from natural sources, have cumulative actions and seriously impair the vital activities of food and game fishes. By continued action these substances, even though they be present in the water in very small

quantities, are often more insidious and far reaching in their effects on fish life than other more obvious pollutants which kill fish at once. Collectively, therefore, the pollution investigations determine the suitability of particular waters, both in the stream and in the hatchery, for various types of fishes, the detrimental actions of specific substances, and reliable means for measuring the condition of the fish themselves.

This year's work has shown, among other things, that very small quantities of arsenicals and several other materials introduced into or placed on waters as mosquito larvacides, impair the growth and nutrition of fishes in these waters in addition to building up serious hazards of lethal poisoning; that certain combinations of some of the less common minerals which are found in small quantities in various western streams are responsible for internal injuries to trout and other fishes in these waters, and that these internal conditions are correlated with decline in weight and finally with the death of the fish in such streams; and that small quantities of several inorganic salts quite widespread in southern and western waters are the cause of low productivity and on occasion of the sudden death of large numbers of fishes in fish hatcheries, streams, and reservoirs receiving such waters.

Because of these findings, and other similar studies in progress, the listing of streams throughout the United States which can be designated as unsuitable for fish plantings, or in which low productivity may be expected because of these biochemical factors, is in progress.

As impounded waters are particularly subject to concentration of the various minerals and other compounds which constitute natural hazards to fish and other aquatic life, the detailed chemical and biological studies which have been in progress for some time at Elephant Butte Reservoir, N. M., and Lake Mead, Nev., have been continued

throughout the past year.

Acute pollution problems continue to claim considerable attention, and specific cases of paper-mill pollution have been studied in Florida, South Carolina, North Carolina, and Minnesota; of phosphatemine pollution in Florida; of copper, lead, and zinc mining operations in Idaho, and Montana; of combined industrial pollution in New York and Mississippi; and of placer gold mining in Oregon. Reports on these investigations have been submitted or are now in preparation. This unit has continued to advise both public and private agencies on matters of pollution and water conditions, and many State officials, various industrial concerns, and numerous private individuals have been given specific answers to particular problems throughout the year.

ICHTHYOLOGICAL INVESTIGATIONS

Fishes of the Canal Zone and Panama.—The study of specimens and data collected in 1935 and 1937 was continued by Dr. Samuel F. Hildebrand. The study of the fresh-water material was completed, and the results have been embodied in a publication entitled "A New Catalogue of the Fresh-Water Fishes of Panama." In this catalogue 127 species are listed, including 9 new ones. The origin and distri-

bution of the fishes of the Isthmus of Panama are discussed, and considerable life-history data are given. A section is devoted to the successes and failures of introduced fishes, setting forth precautions that should be taken and outlining a plan for future introductions.

The study of specimens and data collected in the locks of the Panama Canal, as well as elsewhere in the Canal, was completed. A full report was prepared, listing the animals taken and containing special information on the use of the Canal, especially its locks, as passage-

ways for fishes.

American anchovies.—The taxonomic revisional studies of the American anchovies by Dr. Hildebrand were continued, especially in connection with the work set forth in the preceding paragraph. The study of the Atlantic forms has been carried about as far as the material available will permit, but only a few of the Pacific coast

species have been studied.

Fishes of Tortugas, Fla.—The editorial work and study of specimens necessary in completing and getting ready for publication an unfinished monograph on the fishes of Tortugas, Fla., left by the late Prof. William H. Longley, has been far advanced during the year by Dr. Hildebrand. The points of chief interest in this work are the underwater observations and photographs of the shallowwater fishes, and the numerous additions of West Indian fishes to the American fauna.

General systematic studies.—Revisional studies of the systematics of American fishes were continued by Isaac Ginsburg, with special reference to the Gobiidae. New species were described, based chiefly on material studied from the gobies obtained by Dr. Hildebrand in Panama; material submitted for study by the Bingham Oceanographic Foundation; and material from the Hancock Collection, Stanford University, and from the National Museum.

INDEPENDENT ACTIVITIES OF THE FISHERIES BIOLOGICAL LABORATORIES

WOODS HOLE, MASS.

Owing to the lack of a special appropriation, the Woods Hole station was opened last summer to only a limited number of investigators. In addition to Dr. Galtsoff, Acting Director, and his staff, who were engaged in shellfisheries studies, the following persons occupied laboratory space: Dr. H. M. Smith, Associate Curator in Zoology, United States National Museum, working on otoliths of local fishes and a report on fresh-water fishes of Siam; Dr. Edwin Linton, University of Pennsylvania, helminth parasites of fishes; Dr. Raymond W. Root, College of the City of New York; and Dr. Clark Black, of Swarthmore College, the effect of carbon dioxide upon the oxygen-combining power of marine fish blood; Dr. d'Alto A. Welch, Johns Hopkins University, the variations and distribution of Hawaiian tree snails; Milton J. Lobell, United States Bureau of Fisheries, age composition of the winter flounder population and general studies of the life history; Julian G. Griggs, George Washington University, fertility in the oyster under various conditions.

In September the laboratory sustained considerable damages from wind and a tidal wave which swept the grounds, flooding the basement of the hatchery and the residence and destroying the seawall and pier. No serious damage was done to the floating equipment or to the scientific apparatus.

BEAUFORT, N. C.

Research facilities for the study of marine fishery problems in the South Atlantic region were provided throughout the year at the Beaufort Laboratory. The chief investigations conducted here by the Bureau's staff, under the direction of Dr. H. F. Prytherch, consisted of experiments and studies with reference to oyster culture; destruction of oysters by starfish; the propagation of diamond-back terrapin; the utilization of salt-marsh pools for propagation of fish and shellfish; and mortality of shellfish in Myrtle Sound, N. C.

Assistance and advice was given to the following agencies, as indicated, on matters pertaining to the marine fisheries and fishery industries of the South Atlantic region; United States Engineer Department, construction of new inlets in the vicinity of Cape Lookout for improvement of the fisheries of Core Sound, N. C.; North Carolina Department of Conservation and Development, continuation of oyster-planting programs and investigation of oyster mortality in Myrtle Sound; Duke University, construction of five building units and pier of biological laboratory on property adjacent to the Beaufort stations; Union Carbide and Carbon Corp., continuation of corrosion tests with stainless steel cable under marine conditions; Aluminum Company of America and the United States Navy, antifouling and corrosion tests on aluminum panels; Fordham University, Chemistry Department, tests of the antifouling value of special paints for marine use.

Laboratory facilities for biological research have been provided for 27 independent investigators from other institutions who were engaged in the following studies: Dr. H. V. Wilson, professor in the University of North Carolina, cellular reactions to drugs; Dr. A. S. Pearse, Duke University, assisted by James W. Littler and Henry A. Walker, polyclad worms and crustacean parasites; Dr. Frederick F. Ferguson, University of Virginia, the marine turbellaria; Dr. M. A. Stirwalt, University of Virginia, assisted by Frances C. Smith, morphology of marine rhabdocceles; Dr. George H. Girty, United States Geological Survey, the ecology of living mollusks; Dr. W. C. George, University of North Carolina, comparative hematology; Dr. Bert Cunningham, Duke University, effects of temperature on the rate of development of turtle eggs; Dr. Katherine R. Jeffers, Duke University, the effect of pituitary hormones on the ovaries of marine fishes; Dr. Arthur E. Woodhead, University of Illinois, trematode parasites of fish, especially larval forms in oysters; Dr. F. J. Brinley. North Dakota State College, physiological studies of fish embryos; Dr. William L. Engels, University of North Carolina, terrestrial vertebrate fauna of the coastal banks; A. B. Hardcastle and Margaret S. Hardcastle, a protozoan parasite of the menhaden; Sidney Shapiro, Columbia University, differential growth in the Scombroidei; Coit Coker, University of North Carolina, embryology of echinoderms; Roscoe E. Hill, University of Illinois, ecological studies of marine fauna; Nelson G. Hairston, University of North Carolina,

development and reproduction in hydroids; Russell A. Huggins and Sara È. Huggins, Western Reserve University, the scale size of fish in relation to body size; Gordon H. Tucker, University of North Carolina, gonad development in ascidians; J. Albert Fincher, University of North Carolina, spermatogenesis in sponges; Stephen W. Gray, University of Illinois, physiology of the invertebrate heart; H. J. Lewis and Hervey Lewis, Narragansett Bay Oyster Co., spawning and larval development of oysters.

Propagation of the diamond-back terrapin.—A record hatch of 13,600 young diamond-back terrapins was obtained during the past summer at the United States Fisheries Biological Station at Beaufort, N. C., which operates the world's largest hatchery for the propagation of these salt-marsh turtles. The greatest annual production prior to this time was that obtained in 1935, when a brood of 13,245 was produced in the 5 concrete breeding pens surrounding the sta-Artificial propagation of terrapin was first undertaken here in 1909, and since then has yielded over 128,000 young diamond-backs for restocking the coastal salt marshes of North Carolina and other Southern States. The 1938 brood has been placed in special hibernating boxes in the large rearing house and next spring will be distributed throughout the South Atlantic region in cooperation with

the various State conservation departments.

This year's high production is attributed to improvements that were made in breeding pen arrangements as a result of experimental studies conducted under the direction of Dr. Prytherch and Capt. Charles Hatsel. Since these studies indicated that production of young might be considerably increased by allowing the brood stock greater room for feeding, egg laying, etc., two large pens were constructed to relieve the crowding of adult terrapin in the other five enclosures. In the new pens, in which the brood stock was allowed approximately twice as much space as during the previous year, the production of young by each group (consisting of 400 females and 100 males) increased from 1,200 and 2,480, respectively. in 1937 to 3,360 and 3,616 in 1938. In two other experiments, in which the number of adult terrapin per pen was reduced 50 percent. there were increases of 25 and 40 percent in production of young in In the various experimental pens in which crowding was reduced, the average production of young per female terrapin showed increases of 3.0 to 5.2; 3.0 to 8.41; 6.2 to 8.4; and 8.0 to 10.1, as compared with the previous year. A most encouraging aspect of these improvements in terrapin propagation is that general conditions in 1938 were apparently less favorable for breeding than usual, as two of the "control" pens that were not changed in any respect showed decreases in egg production of 20 and 50 percent.

The total brood stock at present consists of 570 males and 2,025 females, most of which have been in captivity for periods ranging from 10 to 25 years. Last season 320 wild terrapin were added to this stock and are being kept under observation in a separate pen to determine the length of time required to reach satisfactory egg production. During the first summer these terrapin produced only a few young but showed an increased output of 460 for 1938. In experiments conducted in cooperation with Dr. Bert Cunningham, of Duke University, several hundred eggs were successfully incubated under artificial laboratory conditions by keeping them in holders of

moist filter paper instead of in a layer of sand, as in nature. This new technique will be valuable in future experiments to determine the relative importance of various environmental factors such as temperature, humidity, oxygen supply, etc., on the rate of incubation

and survival of young of the diamond-back terrapin.

Utilization of salt-marsh ponds for propagation of fish and shellfish.—Investigations have been undertaken to determine the possibility of using improved marsh areas in the South Atlantic coastal region for breeding and growing mullet, oysters, and other marine species of commercial importance. In cooperation with the Works Progress Administration the construction of a large tidal pond, 21/9 acres in extent, for experimental rearing of mullet was completed by the fall of 1938. This was stocked with over 3,000 fish ranging in size from roe mullet, weighing over 5 pounds, to immature fish having a length of 6 to 8 inches and which are approximately 1 year old. Less than 1 percent of the fish died from injuries sustained during collection and transportation to the pond by live car. tidal circulation renews over half the water in the pond every 12 hours and apparently has maintained, during the first 3 months of operation, satisfactory conditions for breeding and feeding of the This is indicated by the discovery of thousands of very young mullet in the pond during the latter part of December which had attained lengths ranging from one-half to three-fourths of an inch. Representative samples of these small mullet are being collected at intervals of 1 month in order to obtain a record of their rate of growth in this experimental area. Observations are also being made of the growth of the large mullet and the time required for the various age groups or schools to reach marketable size. experiments thus far have shown that tidal ponds of this type can also be used for the temporary storage of comparatively large quantities of live fish until conditions for marketing are most suitable.

Construction operations were continued on marshland adjacent to the mullet-rearing pond to provide shallow canals and small ponds for experiments in oyster culture. These were planted in the early fall with several hundred bushels of seed oysters gathered from nearby beds where overcrowding produces an inferior quality of oyster. In the artificial ponds the oysters have shown rapid growth during the first 3 months, October through December, but the real test as to the practical value of this procedure will come during the summer of 1939, when arrangements will be put into effect to protect these plantings from attachment of spawn and subsequent crowding. Detailed observations of the rate of growth of the seed oysters in weight, volume, etc., are being made by the use of cement panels to which representative groups of oysters have been fastened, in order that individual measurements may be obtained at regular intervals. Different conditions are being maintained and studied in the various ponds with respect to temperature, depth, and circulation of water in relation to the density of oyster plantings and time required for the seed to reach marketable size.

APPROPRIATIONS

The funds for the work of the Division of Scientific Inquiry in the calendar year 1938 were approximately the same as for 1937 insofar as the basic appropriation is concerned. The lifting of the require-

ment for administrative saving, however, made available \$30,000 which was held in reserve the previous year. The sum of \$76,000 was added to the appropriation in order to finance the new Bristol Bay salmon investigation. An appropriation specifically for conserving fish by screens and ladders was provided in the amount of \$20,000. By means of special deposit funds made available by the States of Virginia and Maine, investigations were conducted on the oyster and lobster fisheries, respectively. Large allotments of Public Works Administration and Works Progress Administration funds made possible the construction projects undertaken by the Division to improve the biological stations at Milford, Conn., Beaufort, N. C., and Pensacola, Fla., as well as to construct fish screens in the States of Washington, Oregon, and Idaho. In addition to these projects statistical work on old fishery records was conducted at Cambridge, Mass., Ann Arbor, Mich., and Stanford University, Calif. About one-third of the emergency funds and about one-half of the two regular appropriations was spent in the calendar year 1938. A statement of funds available for biological investigations is given below:

Project	1938	1939	
Regular appropriations: Commercial fishery investigations Oyster cultural investigations Aquiculture investigations Conserving fish by screens and ladders Water quality studies Washington laboratory and administration Total Allotment for travelling expenses Allotment for maintenance and operation of vessels Special funds: Marine fouling studies State of Virginia oyster fund State of Maine lobster fund Public Works Administration projects Works Progress Administration projects	27, 000 29, 000 1, 500	\$222, 300 50, 620 46, 880 20, 000 11, 100 7, 100 358, 000 31, 620 30, 450 5, 000 2, 500 281, 050 127, 645

CHARLES E. JACKSON, Acting Commissioner

Administrative Report No. 36

ALASKA FISHERY AND FUR-SEAL INDUSTRIES IN 1938

By WARD T. BOWER

APPENDIX II TO REPORT OF COMMISSIONER OF FISHERIES FOR THE FISCAL YEAR 1939

UNITED STATES
GOVERNMENT PRINTING OFFICE
WASHINGTON : 1940

ADMINISTRATIVE REPORT SERIES

Since the beginning of the Administrative Report Series, considerable confusion has arisen concerning the system of numbering the separates composing it. Inasmuch as the Reports of the Divisions vary in order from year to year, many have found their designations as "Appendix No. I, II, III, or IV" very confusing. To relieve this, it has been decided to number them as "Administrative Report No. —." Inasmuch as 20 separates had already been printed in this series before starting the numbers, it was deemed advisable to begin the numbering with Administrative Report No. 21. Of course, numbers cannot be printed on those already off the press, but for the information of those who wish to know what the first 25 were, they are numbered for filing purposes as follows:

- 1. Report, Commissioner of Fisheries, 1931.
- No. 2. Alaska Fishery and Fur-Seal Industries, 1930.
- 3. Fishery Industries of the United States, 1930. No.
- No.
- Progress in Biological Inquiries, 1930.
 Propagation and Distribution of Food Fishes, 1931. No.
- No.
- Report, Commissioner of Fisheries, 1932.
 Alaska Fishery and Fur-Seal Industries, 1931. No.
- No. 8. Fishery Industries of the United States, 1931.
- No. 9. Progress in Biological Inquiries, 1931. No. 10. Propagation and Distribution of Food Fishes, 1932.
- No. 11. Alaska Fishery and Fur-Seal Industries, 1932.
- No. 12.
- Progress in Biological Inquiries, 1932. Fishery Industries of the United States, 1932. Propagation and Distribution of Food Fishes, 1933. No. 14.
- No. 15. Fishery Industries of the United States, 1933.
- No. 16. Alaska Fishery and Fur-Seal Industries, 1933.
- No. 17. Progress in Biological Inquiries, 1933. No. 18. Propagation and Distribution of Food Fishes, 1934.
- No. 19. Alaska Fishery and Fur-Seal Industries, 1934. No. 20. Fishery Industries of the United States, 1934.
- No. 21. Progress in Biological Inquiries, 1934. No. 22. Propagation and Distribution of Food Fishes, 1935.
- No. 23. Alaska Fishery and Fur-Seal Industries, 1935.
- No. 24. Fishery Industries of the United States, 1935. No. 25. Propagation and Distribution of Food Fishes, 1936.

Note that the last Commissioner's Report was for 1932. Since then its place has been taken by a reprint from the Report of the Secretary of Commerce under the title "Bureau of Fisheries." Inasmuch as it is no longer a Bureau publication, it is not numbered; but it will be supplied to any who request the Report of the Commissioner for any year since 1932.

Administrative Report No. 36, Appendix II to the Report of the U. S. Commissioner of Fisheries for 1939. Approved for publication June 24, 1939.

INTRODUCTION

The Bureau's work in Alaska, which pertains primarily to fishery and fur-seal management, was continued in accordance with the usual plan. The Commissioner of Fisheries spent several weeks in the Ter-

ritory in July, inspecting both branches of the service.

Regulations for the protection of the fisheries were revised early in the year to meet conservation requirements in various localities, and few additional restrictions were necessary during the progress of the season. In certain places where the salmon runs were late and sufficiently large to assure more than an ample escapement for seeding purposes, the regulations were relaxed to permit from 1 to 4 days additional fishing. Although somewhat below the record output for 1936, the yield of salmon in Alaska in 1938 was well above average.

Weirs for counting the escapement of brood fish were operated in 11 representative salmon streams as a means of determining the ratio of escape to catch. Observations were made also of the numbers of breeding salmon in various important streams where no weirs were

maintained.

Under the authorization granted by the Act of August 2, 1937, for the protection of oyster culture in Alaska, two applications were made for lease of bottoms in Territorial waters of southeast Alaska for the bona fide cultivation of oysters. The leasing of such bottoms is on liberal terms, with a view to encouraging the development of this

industry.

A patrol of the fishing grounds was maintained by the Bureau's 14 vessels, 5 speed boats, and 14 other small power boats, supplemented by a number of chartered boats and launches. Some use was made also of chartered airplane service, both for patrol and for investigational work. There were 134 persons employed for varying periods as stream guards and special workmen in connection with the enforcement of the fishery laws and regulations, in addition to the regular personnel of approximately 60 persons, principally wardens and vessel operators.

Incidental to fishery-patrol duties, attention was given to the clearing of salmon streams in order to make additional spawning areas accessible for seeding. The improvement of conditions for the natural propagation of salmon involved also the destruction of predatory trout that feed upon salmon eggs and fry. This work was carried on chiefly in the Bristol Bay and Cook Inlet regions, through funds con-

tributed by the Territorial legislature and the salmon packers.

Biological studies of salmon, herring, and trout were continued. The studies of the salmon this season were extended to include a comprehensive investigation of the red salmon of the Bristol Bay area.

No change was made in the regulations for the protection of walruses

and sea lions.

There were 58,364 fur-seal skins taken on the Pribilof Islands, an increase of 3,184 over the number obtained in the preceding year. Computations of the fur-seal herd as of August 10, 1938, showed a

total of 1,872,438 animals, as compared with 1,839,119 in 1937. Killings were from surplus male seals, chiefly 3-year-olds, provision being made for a sufficient breeding reserve. The feeding and management of blue foxes on the islands were continued. During the 1938-39 season 1,029 fox pelts were obtained, and a suitable number of animals were marked and reserved for breeding stock.

The operation of the byproducts plant at St. Paul Island for the utilization of fur-seal carcasses resulted in an output of 30,587 gallons of oil and 178% tons of meal. Except for limited quantities retained at the islands, these products were shipped to Seattle, where the oil was sold for commercial purposes, and the meal was turned over to the Division of Fish Culture for use as fish food at the hatcheries.

A few additional buildings for the natives and the fur-seal industry were constructed at the Pribilof Islands, and improved roads between the curing stations and hauling grounds were repaired and extended. Some new structures and equipment were added to the substation for

sea-otter patrol in the western Aleutians.

Through the courtesy of the Navy Department the U. S. S. Vega transported the annual shipment of supplies from Seattle to the Pribilof Islands and brought out the season's take of fur-seal skins on the return trip. The Coast Guard again rendered valuable assistance in maintaining a patrol for the protection of the fur-seal herd and in performing other service.

Acknowledgment is made of the assistance by members of the

Bureau's staff in the preparation of this document.

VISIT OF COMMISSIONER OF FISHERIES AND OTHER OFFICIALS TO ALASKA

The Commissioner of Fisheries sailed from Seattle aboard the Brant on July 2 to inspect the Bureau's fishery and fur-seal activities in Alaska. The party accompanying the Commissioner on this trip included Congressman Millard F. Caldwell, member of the House Appropriations Committee, Dr. Ernest H. Gruening, Director, Division of Territories and Island Possessions, and Mr. John B. McColl, chair-

man of the fisheries committee of the California State Senate.

The Commissioner's party arrived at Cordova on July 9, after stopping en route at various points in southeast Alaska. From Cordova the trip was continued by airplane to Anchorage and the Matanuska colony and thence to Naknek. At this point the party boarded the Coast Guard cutter *Ingham* and proceeded to St. Paul and St. George Islands to observe the fur-sealing operations there. The Commissioner had planned to return to Seattle aboard the Brant, following his visit to the Pribilof Islands, but owing to an accident to that vessel at Kodiak on July 15, the Commissioner's party completed the return trip on the *Ingham*, arriving in Seattle on July 22.

Ward T. Bower, Chief of the Division of Alaska Fisheries, represented the Department on the special fisheries cruise of the Coast Guard cutter *Ingham*, sailing from Seattle on June 24 and returning on July 22. Calls were made at many of the fishing centers and at several Bureau stations en route to Bristol Bay and return. Senator Robert R. Reynolds, of North Carolina, was to have made the trip aboard the *Ingham* but was unable to leave Washington at that time.

Later in the summer, however, Senator Reynolds proceeded to Alaska, and called at St. Paul Island when the Coast Guard cutter Northland

stopped there on July 28.

Seton H. Thompson, Assistant Chief of the Division of Alaska Fisheries, departed from Seattle aboard the *Penguin* on June 11 to study the fur-seal industry at the Pribilof Islands and to inspect the Bureau's fisheries activities in other sections of Alaska. Following extensive observations at St. Paul Island, Mr. Thompson paid particular attention to the fisheries of Bristol Bay, Cook Inlet, and Prince William Sound before returning to Seattle on August 14 aboard the *Penguin*. Harold B. Carr, Editor and Photographer of the Bureau, accompanied Mr. Thompson to St. Paul Island to obtain official pictures of fur-sealing operations. He returned to Seattle with the Commissioner's party aboard the *Ingham*.

JAPANESE VESSELS IN BERING SEA

In the spring of 1938 assurances were given by the Japanese Government that it would suspend the official survey of salmon resources in the waters of Bristol Bay which it had begun 2 years previously, and that it would continue to suspend the issuance of licenses for vessels to fish for salmon in those waters. This disposition of the matter was arranged after prolonged diplomatic negotiations between the countries involved, inasmuch as the expansion of Japanese activities with respect to the salmon fishery had alarmed Bristol Bay packers, and strong protests had been made against the threatened encroachment on Alaska salmon fisheries.

Only one Japanese crab cannery, the *Toten Maru* (2,951 tons), was operated in Bristol Bay in 1938. It was accompanied by 3 50-foot trawlers and 10 launches about 30 feet long, and left the district before the salmon runs began. Thus there was no interference with

the salmon fishery in this region.

The scouting ship Hakuho Maru, of the Department of Agriculture and Forestry, cruised in the vicinity of the Aleutian Islands the latter part of May for the purpose of investigating the migration route of fur seals. The vessel was reported as having arrived at Atka from the westward on May 29 and departed for Japan on June 1, owing to engine trouble.

FISHERY INDUSTRIES

As in corresponding reports for previous years, the Territory of Alaska is here considered in the three coastal geographic sections generally recognized, as follows: (1) Southeast Alaska—embracing all that narrow strip of mainland and the numerous adjacent islands from Portland Canal northwestward to and including Yakutat Bay; (2) central Alaska—the region on the Pacific from Yakutat Bay westward, including Prince William Sound, Cook Inlet, and the southern coast of Alaska Peninsula, to Unimak Pass; and (3) western Alaska—the north shore of the Alaska Peninsula, including the Aleutian Islands westward from Unimak Pass, Bristol Bay, and the Kuskokwim and Yukon Rivers. These divisions are solely for statistical purposes and do not coincide with areas established in departmental regulations.

Detailed reports and statistical tables dealing with the various fishery industries are presented herewith, and there are also given the

important features of certain subjects of special investigation or inquiry.

ALASKA FISHERIES LEGISLATION

Under date of April 7, 1938, the President approved an act amending the Act of August 14, 1937, which prohibited commercial salmon fishing by means of stake or set nets in the Bristol Bay area except by persons having resided continuously for a period of at least 5 years within a radius of 30 miles of the place of set-netting. The new act permits such fishing by persons residing continuously within the said area for a period of 2 years and, in the 1938 season, by persons residing there continuously after June 1, 1937.

The Act of June 14, 1906, entitled "An act to prevent aliens from fishing in the waters of Alaska," was amended by an act approved by the President on June 25, 1938, whereby all fishing in Alaska is limited to citizens of the United States, or to persons owing allegiance thereto, and to certain residents of the Territory. Under this act

only the following persons may fish in the waters of Alaska:

Citizens of the United States.
 Bona fide residents of the United States who have declared their intention to become citizens of the United States.

Natives of Alaska.

4. Aliens owing allegiance to the United States, i. e., Filipinos.

5. Bona fide residents of Alaska who have been residents for a period of three consecutive years prior to June 25, 1938, and who since June 25, 1935, have been continuously or seconally engaged in commercial fishing in Alaskan waters. Aliens in this category, however, may continue to fish only until June 25, 1941, unless in the meantime they declare their intention to become citizens of the United States.

The text of the amendments is as follows:

Be it enacted by the Senale and House of Representatives of the United States of America in Congress assembled, That Public Law Numbered 282, Seventy-fifth Congress, entitled "An Act making further provision for the fisheries of Alaska," approved August 14, 1937 (50 Stat. 639), is amended to read as follows: "That section 1 of the Act approved June 6, 1924, entitled 'An Act for the protection of the fisheries of Alaska, and for other purposes' (43 Stat. 464), as amended, is further amended by inserting in said section at the end of the first proviso thereof another proviso to read as follows: 'Provided further, That in the area embracing Bristol Bay and the arms and tributaries thereof, no person shall at any time fish for or take salmon with a stake net or set net, for commercial purposes, unless such person shall be a citizen of the United States and shall have theretofore continuously resided for the period of at least two years within said area; but for the salmon fishing season of 1938, residence within said area continuously after June 1, 1937, shall be deemed sufficient compliance with the residence requirements of this proviso:"

Approved, April 7, 1938.

Be it enacted by the Senate and House of Representatives of the United States of America in Congress assembled, That section 1 of the Act of Congress approved June 14, 1906 (34 Stat. 263), entitled "An Act to prevent aliens from fishing in the waters of Alaska", is amended to read as follows:

"That it shall be unlawful for any person not a citizen of the United States, or who has declared his intention to become a citizen of the United States, and is not a bona fide resident therein, or for any company, corporation, or association not organized or authorized to transact business under the laws of any State, Territory, or district thereof, or for any person not a native of Alaska, to catch or kill, or attempt to catch or kill, except with rod, spear, or gaff, any fish of any kind or species whatsoever in any of the waters of Alaska under the jurisdiction of the United States: *Provided*, however, That nothing contained in this Act shall prevent those lawfully taking fish in the said waters from selling the same, fresh or cured, in Alaska or in Alaskan waters, to any alien person, company, or vessel then being lawfully in said waters: Provided further, That nothing contained in this Act shall prevent any person, firm, corporation, or association lawfully entitled to fish in the waters of Alaska from employing as laborers any aliens who can now be lawfully employed under the existing laws of the United aliens who can now be lawfully employed under the existing laws of the United States, either at stated wages or by piecework, or both, in connection with the canning, salting, or otherwise preserving of fish: Provided further, That any person owing allegiance to the United States shall not be considered an alien for the purpose of this Act: And provided further, That any person who is a bona fide resident of Alaska and has been such a resident for the period of three consecutive years prior to the date of approval of this Act, and who during such three-year period has been continuously or seasonally engaged in fishing in the waters of Alaska for commercial purposes. the waters of Alaska for commercial purposes, may continue to engage in fishing in the waters of Alaska for commercial purposes for the period of three years after the date of the approval of this Act, although not a citizen of the United States."

Approved, June 25, 1938.

NEW FISHERY REGULATIONS

The regulations for the protection of the fisheries of Alaska, issued February 15, 1938, were amended by the following regulations issued by the Secretary of Commerce under the dates indicated:

[April 27, 1938]

SOUTHEASTERN ALASKA AREA

SUMNER STRAIT DISTRICT

Salmon fishery.—1. Regulation No. 15 (d) is amended to read as follows: Kosciusko Island: West coast within 1,500 feet of a point at 55 degrees 55 minutes 56 seconds north latitude, 133 degrees 48 minutes 22 seconds west longitude.

2. Regulation No. 15 (m) is amended to read on follower (1) Brings of Wales

2. Regulation No. 15 (m) is amended to read as follows: (1) Prince of Wales Island: North coast within 3,000 feet westerly of Point Colpoys; and (2) within 1,500 feet of a point on an unnamed island at the entrance to Port Protection, at 56 degrees 26 minutes 41 seconds north latitude, 133 degrees 38 minutes 4 seconds west longitude.

[June 7, 1938]

KODIAK AREA

Herring fishery.—Regulation No. 3 prohibiting commercial fishing for herring from 6 o'clock antemeridian of Saturday of each week until 6 o'clock postmeridian of the Sunday following is rescinded.

PRINCE WILLIAM SOUND AREA

Herring fishery.—Regulation No. 2 prohibiting commercial fishing for herring from 6 o'clock antemeridian of Saturday of each week until 6 o'clock postmeridian of the Sunday following is rescinded.

SOUTHEASTERN ALASKA AREA

SUMNER STRAIT DISTRICT

Salmon fishery.—Regulation No. 2 (2) of supplement No. 251-24-1 issued on April 27, 1938, is amended to read as follows: Within 1,500 feet of a point on an unnamed island at the entrance to Port Protection, at 56 degrees 20 minutes 41 seconds north latitude, 133 degrees 38 minutes 4 seconds west longitude.

CLARENCE STRAIT DISTRICT

Salmon fishery.—Regulation No. 15 (m) (3) is amended to read as follows: The Bronaugh Islands south of 55 degrees 7 minutes 10 seconds north latitude and west of 131 degrees 43 minutes 30 seconds west longitude.

[July 21, 1938] Bristol Bay Area

Salmon fishery.—Regulation No. 13 is amended to read as follows: Commercial fishing for salmon in the Ugashik district with nets less than 8½ inches stretched measure between knots is prohibited except in the period from 6 o'clock antemeridian June 30 to 6 o'clock antemeridian August 1.

[August 4, 1938] PRINCE WILLIAM SOUND AREA

Salmon fishery.—Regulation No. 10 is amended to read as follows: Commercial fishing for salmon is prohibited during the remainder of each calendar year after 6 o'clock postmeridian August 9: Provided, That this prohibition shall not apply (a) to trolling and gill netting through August 22 in the waters along the western coast from the outer point on the north shore of Granite Bay (known as Granite Bay Point) to the light on the south shore of the entrance to Port Nellie Juan, and (b) to trolling in the period from 6 o'clock antemeridian August 9 to 6 o'clock postmeridian September 20 in the waters of Prince William Sound east of 147 degrees west longitude, exclusive of all waters of Valdez Arm north of Point Freemantle. All trap leads from shore to entrance of hearts must be removed prior to 6 o'clock antemeridian August 13.

[August 15, 1938]

SOUTHEASTERN ALASKA AREA

EASTERN AND WESTERN DISTRICTS

Salmon fishery.—Alaska general regulation No. 1 is hereby amended so as to permit the holding of salmon in traps in the Eastern and Western districts of the Southeastern Alaska area 72 hours after the termination of the fishing season.

[August 18, 1938]

SOUTHEASTERN ALASKA AREA

EASTERN DISTRICT

Salmon fishery.—Regulation No. 7 is amended so as to permit commercial fishing for salmon north of 57 degrees north latitude until 6 o'clock postmeridian August 20.

SOUTHERN DISTRICT

Salmon fishery.—Regulations No. 6 and No. 7 are amended so as to permit commercial fishing for salmon until 6 o'clock postmeridian August 20.

[August 19, 1938]

SOUTHEASTERN ALASKA AREA

WESTERN DISTRICT

Salmon fishery.—Regulations No. 8 and No. 9 are amended so as to permit commercial fishing for salmon south of 58 degrees north latitude from 6 o'clock postmeridian August 19 to 6 o'clock postmeridian August 20.

[August 23, 1938]

SOUTHEASTERN ALASKA AREA

CLARENCE STRAIT DISTRICT

Salmon fishery.—Regulations No. 8 and No. 9 are amended so as to permit commercial fishing for salmon south of a line extending from Approach Point to Caamano Point from 6 o'clock postmeridian August 23 to 6 o'clock postmeridian August 25.

[August 25, 1938]

SOUTHEASTERN ALASKA AREA

CLARENCE STRAIT DISTRICT

Salmon fishery.—Regulation No. 7 is amended so as to permit commercial fishing for salmon between a line extending from Narrow Point to Ernest Point and a line extending from Approach Point to Caamano Point, from 6 o'clock postmeridian August 25 to 6 o'clock postmeridian August 27.

[August 27, 1938]

SOUTHEASTERN ALASKA AREA

CLARENCE STRAIT DISTRICT

Salmon fishery.—Regulation No. 7, as amended by supplementary regulation No. 251-24-9, is hereby further amended so as to permit commercial fishing for salmon between a line extending from Narrow Point to Ernest Point and a line extending from Approach Point to Caamano Point, from 6 o'clock antemeridian August 29 to 6 o'clock postmeridian August 30.

[August 29, 1938]

SOUTHEASTERN ALASKA AREA

CLARENCE STRAIT DISTRICT

Salmon fishery.—Regulation No. 6 is hereby amended so as to permit commercial fishing for salmon north of a line extending from Narrow Point to Ernest Point from 6 o'clock postmeridian August 29 to 6 o'clock postmeridian August 31.

[August 30, 1938]

SOUTHEASTERN ALASKA AREA

SOUTH PRINCE OF WALES ISLAND DISTRICT

Salmon fishery.—1. Regulations No. 6 and No. 7 are hereby amended so as to permit commercial fishing for salmon from 6 o'clock antemeridian August 31 to 6 o'clock postmeridian September 2.

2. Alaska general regulation No. 1 is hereby amended so as to permit the holding of salmon in traps in the South Prince of Wales Island district 72 hours after the termination of the fishing season.

[September 8, 1938]

SOUTHEASTERN ALASKA AREA

SUMNER STRAIT DISTRICT

Salmon fishery.—Regulation No. 6 is amended so as to permit commercial fishing for salmon by means of gill nets and beach seines in Wrangell Narrows, exclusive of all waters within one statute mile of the mouth of Petersburg Creek, from 6 o'clock antemeridian September 12 to 6 o'clock postmeridian September 30.

[September 26, 1938]

KODIAK AREA

Salmon fishery.—Regulation No. 11 is amended so as to permit commercial fishing for salmon between Old Harbor and Kodiak in the period from 6 o'clock antemeridian October 1 to 6 o'clock postmeridian October 15.

ANNETTE ISLAND FISHERY RESERVE

The lease of the fishing and canning privileges of the Annette Island Fishery Reserve by the Annette Island Canning Co. under contract dated April 4, 1933, expired on April 3, 1938. The cannery was again offered to competitive bidders, new proposals being opened on December 15, 1937.

On February 10, 1938, the Assistant Secretary of the Interior, on behalf of the inhabitants of the reserve, entered into a new contract,

effective April 4, 1938, with the Annette Island Canning Co. for the lease of the cannery for 5 years. Under the terms of this contract the Indians are to receive 76 percent of the net profits from the operation of said cannery, and the company 24 percent. The contract provides for a minimum guarantee of \$25,000 to the Indians, regardless of whether or not their share of the profits amounts to that figure, except that this provision shall not be effective if the cannery cannot operate because of strikes, lockouts, or stoppage of labor, or from any other cause legitimately beyond the control of the company, or by reason of action by the Government. There is, however, an unconditional guarantee of \$10,000 to be paid to the lessors, regardless of the net profits during any year in which the \$25,000 guarantee is ineffective due to the above-mentioned causes.

The contract also provides that not to exceed 20 percent of the net profits may be expended by the lessee each year for additions, betterment, and improvement of the cannery, subject to the approval of the Council of the Annette Island Reserve, such expenditures to be repaid to the lessee from the portion of profits accruing to the Indians from

the cannery operations.

In 1938 the company operated eight traps within the reservation the catch of which totaled 1,607,595 salmon, and 35,130 salmon taken in purse seines and gill nets were purchased from the natives. In addition, 1,252,705 salmon were purchased from independent operators of traps and seines outside the reserve. Of the total number of fish obtained, 137,370 were sold to other canneries, and the remainder were packed at the company's plant. In the operation of the cannery and of the fish traps employment was given to 69 whites and 368 natives.

Profits to the Metlakatlan Indians of the reserve on the cannery operations for 1937, under the provisions of the lease then in effect, amounted to \$79,024.41. Preliminary estimates for the year 1938

under the new lease place the figure at about \$63.500.

OYSTER CULTIVATION

Under the authority conferred by the act of August 2, 1937, amending the Fisheries Act of June 6, 1924, with the object of lending appropriate encouragement to the development of oyster culture in Alaska, a 15-year lease, effective July 1, 1938, covering about 100 acres of tide flats in Shoal Cove, Carroll Inlet, southeast Alaska, was executed by the Assistant Secretary of Commerce in favor of William W. Whitcher, of Ketchikan, for the bona fide cultivation of oysters for commercial purposes. This was the first lease of bottoms in Territorial waters under the provisions of the above-mentioned act. A nominal charge is made for such leases, the consideration being at the rate of 10 cents per acre annually.

Application for another lease of oyster bottoms in Alaska was received in December, and a lease was subsequently executed, effective January 1, 1939, covering 75 acres of tidelands in certain waters of George Inlet, Carroll Inlet, Blank Inlet, and Pond Bay, in southeast Alaska, in favor of Celia Fairbanks and Jud Conkle, of Ketchikan.

Beginning in 1931, considerable experimental work has been done in Alaska to determine whether seed oysters may be grown, and the results obtained give fair promise that an industry to supply the local market may be developed.

STREAM IMPROVEMENT

The improvement of salmon spawning streams in Alaska in 1938 was limited, for the most part, to that carried on by stream watchmen in connection with their regular patrol duties, although in the Cook Inlet area some stream-clearing work was accomplished under an allotment of Territorial funds available for this purpose as well as for bounty on predatory trout. The work consisted chiefly in clearing out log jams and other obstructions that hindered the passage of salmon to the spawning grounds. In the removal of obstructions, care is exercised to avoid accelerating the current so as to cause destruction of gravel bottoms used as spawning areas.

In the Kaflia Bay stream, where salmon were having difficulty in ascending long stretches of swift shallow water, construction of additional pools at intervals was undertaken by the Bureau to break the force of the current and facilitate the progress of the salmon upstream.

Increasing numbers of beaver, especially in parts of the Kodiak and Cook Inlet areas, present an important conservation problem. Where necessary, beaver dams have been opened to allow the salmon to ascend to the spawning beds. It is evident, however, that such measures are but temporary, and it is thought that a satisfactory solution to the problem can be found only after due investigation of the potential value of the two natural resources.

CONTROL OF PREDATORY TROUT

The destruction of trout that feed upon salmon eggs and fry has been carried on for a number of years in the Bristol Bay region through funds derived from the Territory and the Bristol Bay packers, the expense being shared equally. Not only has this work resulted in a marked improvement in the runs of red salmon in the region, but it is of material benefit in providing a means of livelihood to residents by furnishing them profitable employment during the winter months. During the year 1938 approximately \$17,000 was expended in the Bristol Bay region for bounty on Dolly Varden trout at the rate of 2½ cents per fish.

In the Cook Inlet area, also, stream improvement and predator-control work have been accomplished through an allotment from the Territorial appropriation and contributions of salmon packers. For the years 1937 and 1938 the sum of \$5,000 was available for this work. In the destruction of predatory trout, efforts were confined to the Kasilof River and English Bay and Kalgin Island streams in order to determine what the possibilities might be. A bounty of 2½ cents each was paid, as in the Bristol Bay region. Less than 10,000 trout tails taken in the Cook Inlet district were vouchered in the summer of 1937, and the number in 1938 to August 26 was 36,388.

Trout traps for the catching of Dolly Varden trout were operated in connection with the four salmon-counting weirs on Kodiak Island. The number of trout taken in these traps was as follows: 51,385 in Karluk River, 54,317 in Red River, and 17,000 in Olga Bay streams.

Scientific studies of Dolly Varden trout in the Kodiak area were continued.

OIL DRILLING IN BRISTOL BAY AREA

Observations were made by Bureau employees of experimental oil-drilling operations in 1938 at the headwaters of Salmon Creek, tribu-

tary to Becharof Lake of the Egegik River system, and the measures that were taken to prevent stream pollution which might impair valuable salmon runs.

These drilling operations were carried on by an association of the Standard, Union, and Associated Oil Companies. During the progress of drilling in July, a pocket of salt water was encountered at a depth of 500 feet. The pressure in the well shaft was 150 pounds per square inch at the surface, necessitating capping of the well, building of sump pools to prevent leakage into Salmon Creek, and cementingin of the well casing to a point below the water stratum to cut off The salt water that was collected in the pools was later further flow. gradually released under direction of the Bureau at the period of high water run-off in the stream. The dilution by fresh water was sufficient to prevent any harm to salmon eggs or fry. In order to assure full protection to the salmon populations in the event that further similar deposits should be encountered, the drilling association voluntarily installed more than a mile of 6-inch pipe to carry any wastes from the well to a point on the Pacific side of the peninsula where they may be disposed of without danger to salmon runs.

STREAM MARKING

New markers defining areas closed to commercial fishing were erected to replace those which had become illegible or damaged, and changes were made in the positions of others to conform with changes made in the regulations with respect to closed areas.

STREAM GUARDS

The Bureau employed 134 men in 1938 as stream guards, weir operators, and special workmen in connection with law-enforcement duties. Of these, 57 were stationed in southeast Alaska, 45 in central, and 32 in western Alaska. Some of the workers were engaged for only a few days, but the average period of employment ranged from 2 to 5 months.

In southeast Alaska 21 stream watchmen furnished their own launches and were assigned to patrol larger bodies of water, or in the vicinity of several streams.

In central Alaska 10 guards were stationed in the Seward-Katalla district, 8 on Cook Inlet, 16 in the Kodiak-Afognak district, 3 at Chignik, and 8 in the Ikatan-Shumagin district. Eight of these guards, most of whom were in the Seward-Katalla district, furnished their own launches.

In western Alaska 29 were on Bristol Bay and 3 in the Yukon-Kuskokwim district.

There were also 11 special employees engaged in scientific work—3 on herring and 8 on salmon investigations. This work was carried on in southeast and central Alaska, as heretofore, and in addition an extensive study of the salmon was begun in the Bristol Bay region.

In addition, there were 12 statutory employees, 50 men on the

Bureau's vessels, and 2 on the chartered boat.

The foregoing makes a grand total of 209 persons identified with fishery protective work in Alaska in 1938, as compared with 236 in 1937.

VESSEL PATROL

Fourteen vessels of the Bureau were engaged in the patrol for the protection of the Alaska fisheries in 1938. Of these, the Auklet, Kittiwake, Merganser, Murre, and Widgeon were used in southeast Alaska; the Eider was in the Kodiak area, the Ibis at Chignik, the Red Wing in the Alaska Peninsula area, and the Coot on the Yukon River.

The Blue Wing was based in the Icy Strait district for a short time in June, then engaged in the patrol and stream survey work on Prince William Sound until August 28, when it was again assigned to southeast Alaska for a brief period before returning to Seattle. As in the previous year, the Crane carried part of the Bristol Bay crew and supplies north from Seattle in May and then patrolled the Alaska Peninsula area until the end of July, after which it returned the Bristol Bay crew to Seattle. The Teal operated on Cook Inlet from May to August, carried on stream survey work in the Prince William Sound area during most of the month of September, and was used in stream survey and general patrol of the Ketchikan district of southeast Alaska during the fall season until October 19.

The Scoter conducted the general patrol of the Bristol Bay area from May 22 to August 3 and then relieved the Crane in the Alaska Peninsula area until August 14, after which it returned to Seattle. In the spring, from March 17 to April 12, the Scoter assisted in the fur-seal patrol off Cape Flattery, Wash., during the northward mi-

gration of the fur-seal herd.

The Brant was used in general supervisory work, chiefly in southeast Alaska. In July it made a trip westward as far as Anchorage. On the return trip to southeast Alaska the Brant on the morning of July 15 ran aground on Williams Reef, about 8 miles east of Kodiak, causing considerable damage. The Navy vessel Teal rendered assistance, towing the Brant to Kodiak and later to Hoonah, in southeast Alaska. The Brant was towed by the Coast Guard patrol boat Alert from Hoonah to Ketchikan, and by the Bureau's patrol vessel Crane from Ketchikan to Seattle, where it was laid up for a number of months. In December, the Brant made a round trip between Seattle and southeast Alaska in connection with hearings on the Alaska fishery regulations at Ketchikan, Petersburg, and Wrangell.

A minor accident reported during the season was the striking of an uncharted rock in Moira Sound by the *Kittiwake* on July 30. The vessel was able to proceed under its own power to Ketchikan, where repairs were made. The work of the *Eider* in the Kodiak district was cut short on August 19 by a broken crankshaft in the main engine, and the vessel was out of commission for the rest of the season. It was towed by the Bureau's vessel *Teal* to Hoonah, and thence by

other Bureau craft to Seattle.

Five speed boats were in operation: No. 1 on Bristol Bay, No. 4 in Prince William Sound, and Nos. 3, 5, and 6 in the Wrangell, Ketchikan, and Juneau districts, respectively. Speedboat No. 6, equipped with a 225-horsepower engine, was in operation this year for the first time. A new 150-horsepower engine, installed in August, greatly improved the service of speedboat No. 4, which had previously been equipped with the 80-horsepower engine salvaged from speed-

boat No. 2 at the time it was destroyed by an explosion in 1935. Fourteen other small power boats were in use also, of which 5 were on Bristol Bay, 1 at Chignik, 2 in the Kodiak area, 2 on Cook Inlet, 2 in the Seward-Katalla district, 1 at Yakutat, and 1 on the west coast of Prince of Wales Island.

In addition to the foregoing, the Wingham was again chartered for patrolling the Copper River flats and, at the close of activities there, for operation on Prince William Sound, and the chartered launch

Marie S was used on the Kuskokwim River.

AERIAL PATROL

Supplementing the regular operations by Bureau vessels and small boats, some use was made of aircraft in the general patrol of traps and fishing grounds. The latter is considered a very effective means of enforcing the fishery laws and regulations, particularly from the standpoint of deterring illegal fishing. Rough water may at times prevent the landing of a plane for making proper investigation when violations are noted, but the possibility of apprehension, when it is known that airplanes are being used for patrol purposes, makes the fishermen more careful to observe the regulations for the protection and conservation of the fisheries.

Chartered airplane service for the patrol of the fisheries in 1938 was furnished by six companies on 23 days. The total flying time was 56 hours, during which the planes traversed 6,246 miles. This patrol included three trips made from Anchorage, covering sections most extensively fished on the east and west coasts of the Cook Inlet area. Twelve and one-half hours flying time were used in the Copper River and Prince William Sound areas, and from 6 to 10 hours each in the Ketchikan, Juneau, Wrangell, and west coast of

Prince of Wales Island districts of southeast Alaska.

In addition, chartered airplane service was used for survey and photographic work in connection with scientific investigations of the salmon which were conducted in the Bristol Bay region in western Alaska from July 23 to October 13, 1938. Transportation was furnished on approximately 25 days during this period, and the total flying time amounted to 102 hours, in which the distance covered was about 9,200 miles.

COMPLAINTS AND PROSECUTIONS

In southeast Alaska a floating trap of Libby, McNeill & Libby near Pulizzi Island was found fishing on July 3 during a weekly closed period. The head watchman claimed he thought the day was Saturday, instead of Sunday. The company, through its attorney, pleaded guilty before the U. S. Commissioner at Juneau and was fined \$600. The following week a floating trap of the Pacific American Fisheries, Inc., at Pt. Alava was found fishing on Sunday. Complaint against the company and the 2 watchmen, Jack Toner and Roger Davies, was filed before the Commissioner at Ketchikan, who fined the company \$500 and sentenced each man to 3 months in jail.

Fourteen purse seine boats were apprehended for illegal fishing in southeast Alaska, and the operators were tried before local U. S. Commissioners, 2 cases being brought before the court at Hoonah, 7 at Ketchikan, and 5 at Craig. In the case against Reuben Eskeberg,

operator of the Cascade, apprehended for fishing within 500 yards of the mouth of a salmon stream in Excursion Inlet, a fine of \$60 was assessed; while in the case of the Louise, found fishing at the mouth of a salmon stream in Tenakee Inlet, the 5 operators, namely, John Kane, Captain; George Paul, William Thomas, Andrew Ibona, and Nicholas Johnson, were fined \$25 each, and fish aboard the vessel were seized

and sold for \$23.08.

Of the defendants tried at Ketchikan, Alex Bryant, captein of the Mary Lou, was fined \$100, and crew members James Scott, John Davis, Jr., William West, and Henry Littlefield were fined \$50 each, for fishing in closed waters at the mouth of Smeaton Creek. Henry Benson, operator of the Joycelyn, was fined \$25 for fishing within 500 yards of the mouth of a salmon stream in Harry Bay after the beginning of a seasonal closed period. A similar fine was imposed upon Ben Ridley, operator of the Empress, for like violations in the same locality, and the salmon aboard the vessel at the time of the appre-

hension were confiscated and sold for \$94.14.

Fines of \$25 each were assessed against Ronald Leask and M. M. Dunlap, operators of the Sea Lad and Helen H, respectively, for fishing within 500 yards of a salmon stream in Thorne Arm during a seasonal closed period, and salmon taken from them were sold for \$26.76 and \$79.95. Lars Larson, operator of the Deloma, was fined \$25 for fishing during a closed period within 500 yards of the mouth of a salmon stream in George Inlet, and his illegal catch of salmon was surrendered and sold for \$112.78 for the account of the Government. A fine of \$25 was assessed against Everett Hudson, operator of the purse-soine boat Mary Eleanor, for fishing in closed waters at the mouth of a salmon stream in Weasel Cove, Boca de Quadra, during a seasonal closed period, and his forfeited catch was sold for \$39.11.

Of the purse-scine fishermen arraigned before the Commissioner at Craig, fines of \$25 each were assessed against Robert Crawford, captain, Lincoln Crawford, and George Mills, of the Spray, for fishing about one-half mile inside the markers at Shipley Bay, and against Alfred W. Willard, captain, Orvalle C. Jones, and Melvin M. Jole, of the 31A655, apprehended at Shipley Bay for carrying shorter seines than the minimum length specified by the regulations. These short seines were ordered sewn together to make one legal seine, and after this was done the seine was inspected by the Bureau's warden.

Three operators of the Lois W—Harry Whitten, captain, Clarence Keily, and Eddie Kahaipo—were fined \$50 each for fishing within 500 yards of the mouth of the Essowah Lake outlet, a red salmon stream on the west coast of Dall Island, and five operators of the Silver Wave, namely, Sid Carle, captain, William Carle, Hugh Baden, Dewey Dudley, and Paul Ozawa, were fined \$75 each for fishing on Sunday at the mouth of a salmon stream in Klakas Inlet. The confiscated fish from these two boats were sold for \$13.30 and \$165.95, respectively. The seine boat 31A985 with a crew of three men—Hermi Valdez, captain, Roy Dado, and Marciana Canote—was found fishing after the beginning of a seasonal closed period in a restricted area in Klawak Harbor, although no fish had been caught. The fine in this case was \$20 each, or a total of \$60, which was paid by the Ocean Packing Co.

Lewis Duval, of Petersburg, was apprehended for fishing in closed waters in Kah Sheets Bay and during a closed period with a beach

seine 30 fathoms long, an illegal type of fishing apparatus in this locality. The above case was dismissed after the defendant was found guilty on another charge and sentenced to 6 months in jail. Another fisherman, Ed Haynes, illegally using a 45-fathom beach seine in closed waters of Lake Bay, was sentenced by the Commissioner at Wrangell to 60 days in jail and fined \$50. At the same time an additional sentence of 30 days in jail, together with a fine of \$50, was imposed against this defendant for fishing without a license, in violation of the Territorial law.

Norman Tate and Hugh Harris, operators of the boat Ann, were apprehended for fishing at the head of Shipley Bay with small-mesh net, which they claimed was a gill net, although it was really a beach seine, not permissible in this locality. In Commissioner's court at Craig the men pleaded not guilty and subsequently, upon recommendation of the Assistant District Attorney, the case was dismissed in view of the fact that the regulations did not specify the size of mesh to be used in gill nets. The operators were warned against further

use of illegal apparatus.

O. R. Batterson, operator of the trolling boat Arline B, apprehended for fishing during a weekly closed period near Cape Chacon, pleaded guilty in Commissioner's court at Ketchikan and was fined \$50, which fine was suspended. Pascual Roma Niere, who engaged in trolling for salmon commercially during a weekly closed period, pleaded guilty before the Commissioner at Wrangell and was fined \$50 and sentenced to 30 days in jail. Four king salmon taken by him were seized and sold for \$3.63. This defendant also was found guilty of violation of the Territorial law on two counts, namely, being an alien and fishing without a license, for which he was fined \$50 and sentenced to 30 days on each count, the jail sentences to run concurrently with that imposed for violation of the Federal law.

Two cases were brought before the local Commissioner against residents of Yakutat for fishing with set gill nets less than 100 yards apart. One of these violations involved nine persons, as follows: Henry Shodda, Moses Milton, Ned Williams, David Henry, Paul Henry, Jack Reed, Eugene George, Richard Reese, and Tom John In the other, the following four persons were concerned: David Abraham, Mary Henninger, Sam Bagge, and George Valle. All were found guilty, and fines of \$30 each, with costs, were assessed. In the case of Henry Shodda, however, the fine and costs were suspended

pending good behavior, as he was new in the area.

George Anderson and Oscar Peterson were apprehended in the vicinity of Monte Carlo Island, Keku Strait, for possessing illegal fishing gear consisting of a 25-fathom beach seine. Each was given

a 90-day suspended sentence, and the seine was destroyed.

Several pieces of fishing apparatus were found that were evidently being used in violation of the fishery laws and regulations, but the owners were not apprehended. This apparatus included a 20-fathom seine found cached on the bank of a stream tributary to Calder Bay; a trap constructed across the Essowah Lake stream and a 25-fathom seine nearby; a piece of old gear stretched across Andrews Creek near Wrangell; a small gill net, a 10-fathom line, and about 10 fathoms of chicken wire in Klakas Lake stream; and a 75-fathom gill net in Sumner Strait. Except for the last-mentioned gill net, which was turned over to the marshal, this apparatus was destroyed.

The case against the Lindenberger Packing Co., of Craig, for canning fish more than 48 hours after their capture in the 1937 season, which was continued until the spring term of court in 1938, was dismissed. In the case pending at the close of 1937 against Frank Richardson, charged with fishing with a small seine at the mouth of Blind River, Wrangell Narrows, a trial by jury, at the defendant's request, was held on August 8, 1938. The defendant was acquitted on the plea that the markers were not at the mouth of the stream but that the tide

backs up 1½ miles above them.

In the Seward-Katalla district, 11 cases of illegal fishing, involving 14 persons, were brought before Commissioner's court, and convictions were obtained and fines imposed in all instances except one. Of these cases, one involved the taking of undersized clams for commercial purposes by A. W. Marcus, who was fined \$25. His forfeited catch, amounting to 452 pounds, was sold for \$24.86. There were four cases of illegal seine fishing for salmon, as follows: Jack Brady, fishing with a skiff and seine during a weekly closed period, fined \$100; Oscar Donaldson, fishing aboard the Katherine L during a weekly closed period in a restricted area at the head of Eaglek Bay, fined \$75; Arthur G. Clark and William Imlach, fishing with seine boat 31 B839 in the mouth of a salmon stream in Hawkins Cutoff, fined \$50; and William Stears and Clarence Betchel, fishing with the Cambria inside

markers at the mouth of lagoon in Eaglek Bay, fined \$50.

Six violations in the Seward-Katalla district involved the illegal use of stake or set gill nets in sloughs of the Copper River area which were closed to commercial fishing. In one case, that against William P. Smith, operator of the boat 31D463, observed in Pete Dahl Slough by the Bureau's warden while on airplane patrol on June 11, the defendant denied any knowledge of the set net, and the case was dismissed for lack of sufficient evidence. In the other cases pleas of guilty were entered in Commissioner's court and a fine of \$75 was assessed against each defendant, as follows: Harold Couzins, operating stake net in Walholla Slough on May 24; Charles Christensen, set netting in Pete Dahl Slough with the boat 31 B540 on June 11; Otto Tiedeman and Emil Freeman, using set nets in Pete Dahl Slough on June 11; and Wilbur Platt, with the boat 31 A956, and Gilbert Young, with the boat 31 B353, using set nets inside Mountain Slough on July 8. One hundred and twenty-one red salmon in the possession of Harold Couzins at the time of his apprehension were sold for \$33.28. A catch of 451 red salmon was surrendered also by Messrs. Tiedeman and Freeman and sold for the account of the Government for \$124.03.

In the Cook Inlet area six cases of violations of the regulations were reported, most of which were observed by means of airplane patrol. A trap owned by the Cook Inlet Packing Co. and located about 15 miles north of Ninilchik Village was found with the tunnel not closed and the heart walls not lifted or lowered during a weekly closed period in accordance with the method prescribed by section 5 of the Act of June 6, 1924. Complaint was filed before the Commissioner at Seldovia against both the company and the trap watchman, Simeon Oskolkoff. The latter admitted the charge but claimed his timepiece was wrong. He was fined \$100. The company, through its manag-

ing owner, pleaded guilty and was fined \$200.

Otto Rensing, operator of power boat 31C40, found fishing with a beach seine inside markers at the mouth of Chinik Creek on July 13,

was taken before the Commissioner's court at Seldovia, where he pleaded not guilty. As he had been apprehended with others earlier in the season fishing in McNeil Creek and had been dismissed with a warning, he was bound over to the District Court under \$500 bond. When the case came before the Grand Jury in November, it returned a nontrue bill.

Fines of \$50 each were assessed by the Commissioner at Anchorage against Buster Ephin and George Johnson, apprehended for operating set gill nets during a weekly closed period in Cook Inlet, the former having three set nets about 5 miles southwest of Point Possession on June 13, and the latter using a set gill net on June 6 and two of such

nets on June 13 in Lewis River Slough.

Prosecutions were brought before the Commissioner at Seldovia against Michel McDonough and Frank Manton for operating three set gill nets about three-fourths mile south of Cape Kasilof during a weekly closed period. The latter claimed sole responsibility for the violation and pleaded guilty as charged. The court assessed a penalty of 30 days in jail and suspended the sentence. An anchored gill net. found fishing between Beluga River and Three Mile Creek during a weekly closed period, was seized and 10 king salmon therein were sold for the account of the Government. Later it was learned that the net belonged to Mrs. T. B. Ryan and that she was fishing for her dogs. After due investigation and conference with the United States Attorney, the net and the money received from the sale of the salmon were returned to the owner.

In the Kodiak area, two gill-net fishermen, Frank Marshall and Mike Naumoff, were arraigned before the Commissioner at Kodiak for fishing in Olga Bay during a weekly closed period. They pleaded guilty and were fined \$25 each. Operators of three purse seine boats in this area also were brought before the Commissioner's court at Kodiak, where they pleaded guilty and were fined, as follows: Pat Gowan and L. Rachford, fined \$25 each for setting seine from the Jaquelin alongside another purse seine in the Karluk district, after having been warned to observe the 100-yard distance interval; and Edwin Liljegren, operator of the L & W, and Ben Durkee, operator of the Triton, fined \$75 and \$100, respectively, for fishing along Seven Mile Beach during a seasonal closed period. Seized fish, consisting of 2.411 pinks and 160 chums, from the L & W were sold for \$123.70, and 3,439 pinks and 803 chums from the Triton were sold for \$195.03.

In the Alaska Peninsula area, the purse seine boat Blanche, commanded by John Bacoka, was apprehended on June 17 for fishing about one-quarter mile from a salmon trap in East Anchor Cove. Upon trial before the Commissioner at Squaw Harbor, the defendant pleaded guilty and was fined \$75, with a warning also that any future violations by operators in the district would receive sterner action. Fish aboard the vessel at the time of the seizure were valued at less than \$3 and were not confiscated. Andrew Hotovitsky, beach seiner commanding the gas boat Swinomish, was apprehended on July 22 for fishing in closed waters at the mouth of a salmon stream in Little He pleaded guilty in the Commissioner's court and was fined \$200. His forfeited fish, consisting of 1,238 chums and 294 pinks, were sold for \$82.37.

Evidence of illegal fishing in Thin Point Lagoon resulted in investigation of Andrew Hotovitsky and Alex Bendixsen. Circumstances surrounding the cases prevented any conviction. Mr. Bendixsen was released with a warning, and Mr. Hotovitsky was ordered to appear some time later in Commissioner's court at Squaw Harbor, although his fishing gear was not seized and he was allowed to continue fishing. Meantime the case was reviewed by the Commissioner and, owing

to insufficient evidence, it was dismissed without a hearing.

No violations of the Federal fishery laws and regulations were reported for Bristol Bay. In this area, however, 115 complaints were filed against alien fishermen under the Territorial law (Chapter 30, Session Laws of Alaska, 1933), on which there were 62 convictions. Fines totaling \$10,600 were collected, and suspended fines amounted to \$350. Jail sentences were enforced in 58 cases and suspended in 4 cases.

TERRITORIAL LICENSE TAX

Fisheries license taxes were collected by the Territory under the general revenue law of 1921, as amended in subsequent sessions of the Territorial Legislature. A statement from Oscar G. Olson, Territorial Treasurer, under date of June 6, 1939, gives the collections made to that date for the year 1938, representing the taxes on operations of the previous year. It was stated that collections under the several schedules were fairly complete, although a few of the fisheries companies had not yet made full settlement.

It will be noted that the following schedule includes the amounts collected for clam diggers' and fishermen's licenses, which have

previously been omitted from the report.

Fishery license taxes collected by Territory for fiscal year ended Dec. 31, 1938

Schedule	Division No. 1	Division No. 2	Division No. 3	Total
Salmon canneries (pack)	\$150, 765. 01	\$22.00	\$512, 426. 21 355. 83	\$663, 213. 22 355. 83

KUSKOKWIM RIVER

A patrol of the Kuskokwim River was maintained by Theodore R. Lambert, with the chartered launch Marie S, from the first of June

until the end of August.

King salmon appeared at the mouth of the river on May 20, or somewhat earlier than usual, and the run continued steady through June, after which a few late stragglers were taken until the end of July. Most of the kings taken by natives, particularly near the mouth

of the river, are for daily use, as they require more time and attention

for drying than do other species.

Both chum salmon and reds were unusually abundant this year. A heavy run of chums started on June 19 at the mouth of the river and continued strong until the middle of July, when it dropped off sharply. The bulk of the red-salmon run entered the river between July 1 and July 15. Toward the end of July a few cohos were taken in the vicinity of Bethel, and a good run began on August 1, which continued heavy for only a few days while a southwest wind prevailed. Stormy weather throughout August made it impossible to dry cohos except under cover in the smokehouses. All natives who fished with any regularity had previously caught and cured sufficient fish for their winter use, and many disposed of a surplus to traders. The latter by the end of July had obtained all they could handle during the winter.

Fishing apparatus used by the natives between the mouth of the river and the Narrows consists mainly of set nets, from 9 to 30 fathoms in length. Drift nets are not considered practical for general use in this locality because of the extreme width of the river and the many bars and channels. Much of the time it is too rough offshore for the use of small boats. Between the Narrows and Tuluksak the bulk of the catch is taken by drift nets, from 25 to 50 fathoms in length, although set nets are used to some extent. Upstream above Akiak the current is stronger and the fish wheel is the main gear, with comparatively few drift and set nets in use.

The only commercial fishing operation in the district for the outside market was that of Robert Gierke, who reported an output of 6 tierces of pickled cohos and 12 tierces of pickled kings. Three hundred and eighty natives fished in the river for local food requirements, using 520 gill nets of 13,499 fathoms, 47 wheels, and a number of small boats. They prepared 243 tons of dried chums, 22 tons of dried kings, and 21

tons of dried reds.

YUKON RIVER

Three outfits prepared mild-cured salmon on the Yukon River for the outside market, as follows: Northern Commercial Co., which operated on a barge in Acheron Channel; St. Mary's Mission, at the head of Sunshine Bay in Acropok Slough; and Chris Lauridsen, at Kwiguk Slough. Their total output of mild-cured salmon was 198 tierces of kings. The fish used by the Northern Commercial Co. were taken in gill nets outside the mouth of the Yukon River by native fishermen; while those handled by the other two operators were taken in the river by wheels and gill nets, respectively.

were taken in the river by wheels and gill nets, respectively.

Inspector Calvin F. Townsend and a stream guard patrolled the district aboard the Coot, leaving Nenana on May 26 for the mouth of the Yukon and returning to Nenana on September 18. During the trip downstream the water was at low stage, with very little driftwood. At that time there was little activity at the camps, as the inhabitants were out hunting beaver and muskrats. In general, the supply of dried fish from the previous season had not lasted through the winter, but plenty of whitefish had been caught by means of traps through the

ice.

The first king salmon were caught at the mouth of the Yukon on June 1, but the main run began on June 5 and continued good until

July 15. Chum salmon came into the river at the same time, and the runs of both species were unusually heavy. Beluga whales were more numerous than for many years and did considerable damage to salmon nets. Several of these whales were taken by the natives to

supplement their regular supply of food.

As a result of the excellent runs of king and chum salmon and the good weather for drying fish, natives on the lower river had all the fish they needed for winter. The catches at camps in the upper reaches, however, were not uniformly good. In some places the catches were above average and in others very poor. An explanation for the light catches of kings at certain points was that the fish seemed to follow the main channel up the river and did not strike in close to shore, so they were not taken in the wheels and nets.

There was a marked shortage of salmon on the Tanana River, and the only camp which had any success in fishing was one about 8 miles from Tanana, where fair catches of cohos were obtained from the last week of August until the middle of September. Very few of this species were taken along the Yukon because of high water and heavy driftwood. As a result of storms in August the Tanana River was at

flood stage from about the 10th to the end of the month.

Products of the Yukon and Tanana fisheries, including those shipped to the outside market, were as follows: 280 cases of king salmon canned; 198 tierces of mild-cured kings; 17,300 pounds of dry-salted kings; and 213 tons of dried chums. Apparatus consisted of 194 wheels, 88 gill nets of 2,100 fathoms, 3 motor vessels of 43 tons, 1 launch, 9 gill-net boats, 1 scow, and miscellaneous small boats. There were 11 whites and 382 natives engaged in the fishery.

WEIRS FOR COUNTING SALMON ESCAPEMENT

The maintenance of weirs through which the escapement of brood fish may be counted provides information of value in the study of the life history of the salmon and in the regulation of commercial operations to prevent any impairment of the runs through inadequate

seeding of the spawning beds.

Eleven weirs were operated in representative streams of Alaska in 1938, and a count of salmon was again made at the Kalgin Island stream without the use of a rack. It was the purpose, also, to reestablish the weir in Chignik River, which had been operated each season since it was first placed there in 1922, but unusually high water for a prolonged period made all attempts to construct it unsuccessful.

Reports of the weir operations and the counts of salmon in 1938

were as follows:

ALITAK BAY

Two weirs were again established on Olga Bay, tributary to Alitak Bay, construction of the cannery station weir being completed on May 26 and the upper station weir on May 29. At each place the counting of red salmon began on the day the weir was ready and was continued until the structure was removed on August 29. count for the season at the upper station weir consisted of 616,064 red salmon, 3,371 pinks, and 9,085 cohos. Corresponding figures for the cannery station weir were 97,455 red salmon, 23,701 pinks, and 371 cohos.

In the latter part of July the catch of red salmon in the Alitak Bay district was substantially larger than the escapement. Olga and Moser Bays, therefore, were closed to commercial fishing at 6 p. m. on July 30 and reopened at 6 a. m. on August 13. During that interval approximately 319,000 red salmon were counted through the weirs, the bulk of the escapement being during the second week and reaching its peak on August 13, when 61,541 fish of this species were tallied.

A trout trap operated at the upper station weir took 10,047 Dolly Varden trout during the season, and one at the cannery station took 6.953 of these predatory fish.

Work at the cannery station weir was carried on by Morris Rafn, and at the upper station weir by Lloyd Burns, under the direction of

Warden J. Steele Culbertson.

CHIGNIK RIVER

No weir was maintained in the Chignik River in 1938, as it was impossible to establish the structure because of high water. After repeated attempts to construct it were unsuccessful, the work was finally abandoned toward the end of June.

In general, there was a rather light run at Chignik during the season. The commercial catch was 407,605 red salmon, and it was estimated that 550,000 of that species escaped to the spawning grounds. The early escapement was good, owing to the fact that salmon traps were not installed until the latter part of June. Chignik Lagoon and part of Chignik Bay were closed to commercial fishing from 6 a. m. August 15 to 6 a. m. August 19, in addition to the closed periods specified by the regulations.

CHINIK CREEK

From July 6 to July 29, inclusive, 3,804 red salmon were counted through the weir at Chinik Creek, and it was estimated that 200 reds were in the stream below the weir at the time the structure was removed. The peak of the run was on July 25, when 1,008 salmon were tallied. Irwin Metcalf was in charge of operations, under the direction of Capt. R. L. Cole.

ENGLISH BAY

The count of salmon in the stream at the head of English Bay began on June 8 and continued through August 13, during which time the total escapement numbered 16,779 red salmon. The largest count for any one day was 806 on July 26. Weir operations were carried on by Percy G. Malthie until August 6, and then by Irwin L. Metcalf, under the supervision of Capt. R. L. Cole.

FISH CREEK

Counting operations at the weir in Fish Creek were carried on from July 10 to August 8, inclusive, the total number tallied consisting of 182,463 red salmon and 19,417 cohos. The latter species began to ascend on July 24 and were estimated to be 10 percent of the total

count for the first week and 20 percent thereafter, as it was impossible for the operator to make an exact count of each species. The bulk of the red salmon escapement passed upstream in the period from July 22 to August 1, reaching a peak on July 23, when 23,540 fish were counted. Jack Tansy was assigned by Capt. R. L. Cole to perform the work at this weir.

KALGIN ISLAND CREEK

As in previous years, the stream guard stationed near the salmon stream on the east side of Kalgin Island made a count of the red salmon escapement, although no weir was established in that stream. From June 15 to August 3, inclusive, there were tallied 5,046 red salmon, about one-third of which passed upstream during the last week in July.

KARLUK RIVER

Construction of the weir in Karluk River was begun on April 9 and completed on April 13. Although virtually all ice had gone out of the river, high water made the weir construction rather difficult. Both red and king salmon began to pass upstream on May 19, but the numbers were small until June 8, when a very good run set in. Within the next 3 weeks more than 700,000 red salmon were counted through the weir, the run reaching its peak on June 18, when 83,102 salmon were counted. The large escapement during this period was owing partly to the fact that very little fishing was being carried on, as operations in the district had been delayed on account of the strike of cannery workers.

Pink salmon appeared off the mouth of the river on July 17 and began to pass through the weir two weeks later. A very heavy run of pinks entered the river during August. Owing to the large number of spent fish coming downstream, it was impossible to keep the weir closed after September 3, and the structure was finally removed on

September 26.

The total escapement for the season consisted of 1,075,678 red salmon, 1,714,589 pinks, 40,000 cohos, and 5,606 kings. These figures include an estimated escapement of 200,000 reds, 75,000 pinks, and 40,000 cohos during the period from September 4 to September 26, when the weir was left open. Commercial fishing in the Karluk district was closed on September 3 for the remainder of the season, in order to assure a 50-percent escapement. The total commercial catch of red salmon from the Karluk run was 976,904.

In connection with the operation of the Karluk weir, traps were installed for the capture of Dolly Varden trout, and 51,385 of these

predatory fish were taken during the season.

Weir operations were in charge of James O'Brien, under the direction of Warden J. Steele Culbertson.

KLAWAK CREEK

Construction of the weir in Klawak Creek was completed on May 24 and counting operations began on the following day, when a few red salmon passed upstream. This run was light but fairly steady throughout the season. On August 10 the first pinks and cohos were

tallied. The run of pink salmon reached its peak on September 16, when 64,119 fish of this species were tallied through the weir. The total escapement numbered 357,751 pinks, 22,209 chums, 15,368 reds, and 4,398 cohos, including an estimate of 15,000 pinks, 4,000 chums, and 1,000 cohos on September 26. Heavy rains the night of September 25 caused the creek to rise about 4 feet, as a result of which the weir was damaged beyond repair for the season. Lloyd M. Johnson was weir foreman, under the direction of Warden Donald S. Haley.

LITTLE PORT WALTER

At the Little Port Walter weir, operated in connection with the biological study of pink salmon in southeast Alaska, there were counted 6,467 pink salmon, 5 chums, and 1 coho in the period from August 29 to September 22, inclusive. It was estimated that 200 salmon were in the bay when the weir was removed.

ORZENOI RIVER

From June 14 to Aug. 7, inclusive, there were counted at the weir in Orzenoi River 8,675 red salmon, 1,764 pinks, 510 chums, and 40 kings. The peak of the run was on July 17, when 1,427 red salmon passed through the weir. During most of July the stream was low, as there was little rainfall. Gordon Ashton carried on the weir work at this place, under the direction of Acting Warden Mark Logan.

RED RIVER

King salmon began to pass upstream through the Red River weir on May 21, and reds on May 25. The run of red salmon was somewhat smaller than in other recent years, the total count for the season numbering 185,851. Other species tallied were pinks, 406,725;

kings, 4,465; and cohos, 2,169.

Counting operations were continued until heavy rains caused the river to rise over the top of the weir on August 25. As the structure was badly damaged, its removal was begun on the following day when the high water subsided. There was a fair showing of salmon in the lagoon and some outside the river in the strait at that time. It was estimated, therefore, that the total escapement of reds would be more than 200,000. The Red River district was closed to commercial fishing for salmon after August 13, as the catch was then considerably in excess of the escapement.

Two trout traps operated in connection with the weir caught 54,317

Dolly Varden trout during the season.

The work at this place was in charge of Woodrow Buckley, under the supervision of Warden J. Steele Culbertson.

SITUK RIVER

Construction of the weir in Situk River was completed on June 7, and the first red salmon were counted on June 12. No count was made from June 18 to June 25, inclusive, as the weir was out of commission during a period of high water. As soon as the river fell sufficiently, the weir was dismantled and reestablished about 30 feet above the former site. Counting was resumed at noon on June 26 and con-

tinued through August 2, when the weir was removed because of high water and anticipated floods which threatened a loss of materials. The total count numbered 169,333 red salmon, 28,319 pinks, and 2,668 kings. A. W. Tveter carried on the weir operations under the direction of Warden William B. Berry.

SALMON TAGGING

A salmon-tagging experiment was conducted in southeast Alaska in 1938 to develop further information concerning the migration routes of pink salmon through lower Chatham Strait. Approximately 2,100 mature pink salmon were tagged from July 7 to Aug. 12, inclusive, the work being done at traps in Tebenkof Bay by employees of the Division of Scientific Inquiry. Of the total number tagged, 637 salmon, or slightly more than 30 percent, were recaptured by the commercial fishery. It is planned to conduct a similar experiment in 1939 to determine any differences in the migration routes of the

pink-salmon runs in even- and odd-numbered years.

In the 1938 season, also, a tagging experiment was carried on in the Kodiak area to determine the length of time the fish take to travel from Alitak Bay to weirs in Olga Bay. As commercial fishing is controlled by the weir count, it seemed advisable to determine the lag between catch and counted escapement. Seven hundred red salmon were tagged at the Bun Point trap of Pacific American Fisheries on June 28, and 458 were tagged on July 29 at the Miller Island trap. The work was done by Associate Aquatic Biologist Joseph T. Barnaby and Junior Aquatic Biologist Allan C. DeLacy, assisted by the crew of the Eider and Stream Watchman Morris Rain. A red streamer-type tag, designed by Messrs. Barnaby and DeLacy, was used for the first time in this experiment. The tags were attached to the dorsal part of the body just posterior to the dorsal fin and were readily observed as the fish passed through the weir.

Of the fish tagged in the Kodiak area in June, less than 5 percent were observed subsequently at the weirs, while nearly 50 percent of those tagged in July were counted. A closed period from Aug. 1 to 12 in the commercial fishing season aided in obtaining a larger escape-

ment from the latter tagging.

The fish tagged in June took an average of 7 days to go to the cannery station, and 9 days to the upper station. In the second experiment, however, the fish took an average of 17 days to go to the cannery station, and 11 days to the upper station. No explanation can be given as to the relatively short period taken to reach the upper station, compared with that taken to reach the cannery station. This investigation indicates that the fish arrive at the weirs from 1 to 2 weeks after they pass the fishing gear in Olga Bay.

SALMON LIFE-HISTORY STUDIES

Studies of the life histories and fluctuations in abundance of the Pacific salmon in Alaska were continued in 1938 by the staff of the Fisheries Biological Station at Seattle, Wash. The major investigations of the red salmon at Karluk and the pink salmon at Little Port Walter were carried on as formerly. In July 1938 an appropriation was made available for a comprehensive and extended investigation

of the red-salmon fisheries of Bristol Bay. This investigation consisted of two distinct parts, one dealing with the marine factors influencing the migration of the salmon and their availability to the commercial fishery, and the other dealing with the fresh-water life history and survival of the young in the lakes and streams.

Biological data concerning the red salmon were collected at Chignik and Copper River stations, as in past years. Studies carried on at Karluk River and Little Port Walter gave further insight into the natural factors that influence the abundance and survival of the

salmon.

The studies concerning the influence of predatory trout at Karluk River and neighboring streams on Kodiak Island were continued. The tagging of these trout shows that they do not have the high degree of homing characteristics of salmon, but they wander back and forth between the streams on Kodiak Island.

Through the efforts of the C. C. Workers, as directed by the Forest Service, the station at Little Port Walter was greatly improved by the construction of trails to the headwaters of the stream and of a dock with floating mooring for the accommodation of large boats that visit the field station. The Forest Service also used the stock of acclimated rainbow trout in Sashin Lake, one of the lakes at the head of the stream, for transplantation in many lakes on Baranof Island, and also for a stock sent to Fairbanks.

The collection, compilation, and analysis of the records of daily catches of salmon throughout Alaska by the principal types of fishing apparatus were continued in 1938 and, as in previous years, provided information as to the fluctuations in abundance and time of appearance of the runs in various districts. Considerable effort was made also in securing additional historic material and records on the fisheries of Bristol Bay in connection with the newly developed investigation of the red salmon in this area. The information secured from this work, as in previous years, was used in recommendations for changes in the fishery regulations throughout the Territory for properly conserving salmon populations.

OBSERVATIONS ON THE ESCAPEMENT OF SALMON

The so-called "White Act" of June 6, 1924, established the intention and policy of Congress that not less than 50 percent of the salmon runs in Alaskan waters should be permitted to escape. In certain representative streams counting weirs are operated to accurately fulfill this requirement. Where the operation of weirs is not feasible the development of runs is closely observed so that regulations may be modified during the season if necessary, to secure the most desirable spawning escapement. There follows a general summary of salmon runs and escapement in each of the fishing areas of Alaska.

Southeastern Alaska.—The late appearance of pink salmon runs in southeastern Alaska was characteristic of the even-year cycle of this species in recent years. A prolonged dry season in August, and the consequent low level of streams, retarded the ascent of salmon to spawning areas, but heavy rains after the first of September relieved this condition in all districts. The fall survey of spawning grounds was hampered in many cases by the swollen condition of streams.

In the Ketchikan region, embracing the southern district and that part of the Clarence Strait district south of Ernest Point, the run was of average proportions and considerably better than in 1937. As in past years, the run appeared several days earlier in the southern district than in Clarence Strait, and in both sections it was at its peak as the fishing season closed. Stream inspections indicated a rather spotted seeding, but these districts generally appeared to have obtained adequate escapements. In the southern district the better spawning areas were well seeded, particularly streams in Very Inlet, Boca de Quadra, Smeaton Bay, and Rudyerd Bay. In the western portion of Behm Canal a good escapement of reds and a fair seeding of pinks were observed on the spawning grounds at Loring and Yes Bay. In the Clarence Strait section fair escapements were noted in Tolstoi Bay and Thorn Bay, while streams in Kasaan Bay, Cholmondeley Bay, and Moira Sound were well seeded.

In the Wrangell district, including the waters of Sumner Strait and Clarence Strait, north of Ernest Point, the run fell considerably short of last season and was the smallest that this district has seen in recent years. Indications are that additional protective measures are necessary to restore this run to its former abundance. A survey of streams in this area revealed a rather light escapement, but there appeared to be a fair seeding of the better spawning areas. particularly in Anan Creek, Salmon Bay, Bradfield Canal, and Totem Bay. A good run of reds and cohos occurred in the Stikine River area and the escapement there was believed to be ample for seeding purposes.

There was no heavy sustained run at any time during the season in the South Prince of Wales Island district. Pinks appeared in small numbers about August 13, and after August 27 there was a fair showing of this species off Dall Island, Cordova Bay, and Trocadero Bay. The run of sockeyes, while considerably better than in 1937, was below normal, and chum and coho runs also were disappointing. The total count of each species through the Bureau's weir in Klawak Creek was substantially below the average escapement in recent years. Spawning areas in Tuxekan Passage were well seeded, however, compared with the 1937 season, and Sarkar Lakes, Deweyville, El Capitan Passage, Calder Bay, Sea Otter Sound, and Davidson Inlet all had fair escapements.

On August 1 and 2 a good showing of pinks in Cross Sound proved to be only a spurt which tapered off as the run reached the inner section of Icy Strait and spent itself. The main body of pink salmon entered Icy Strait after fishing operations had been terminated in that district, and moved into the inner waters of Chatham Strait and Frederick Sound about the middle of August. The sun was heavy but of short duration and the escapement in the streams of Icy Strait was below normal. In the Western district, streams tributary to Chatham Strait were found to be well seeded with pinks, except in the Hawk Inlet area, where the escapement was poor. The streams inspected in the Eastern district indicated a good escapement for that section also, although the survey there was hampered by heavy rains and high streams. All three sections of the Juneau district experienced average runs of reds and cohos, and the escapement of these species was generally satisfactory. Chums were less abundant than in other years, however, and the seeding of this species was below normal.

The Yakutat area had a better than average run of reds and kings this season, especially in Dry Bay and Situk and Ahrnklin Rivers. escapements were reported for all important species in this area.

Prince William Sound and Copper River region.—The run of pinks was unusually late in Prince William Sound but developed rapidly after July 24, reaching large proportions in all sections during the last few days of the season. Pinks were so abundant throughout the area as the close of the commercial fishing season approached, that the Secretary of Commerce approved a supplementary regulation extending the season 2 additional fishing days. A survey of representative salmon streams indicated an excellent seeding of pinks in most spawning areas. Unusually heavy escapements were observed in the northern and eastern sections of the Sound.

A good run of red salmon occurred in the Copper River area. reaching its peak shortly after the first of June. The escapement to the upper river was very satisfactory, owing partly to the stormy weather that hampered fishing operations and reduced the commercial

take.

Cook Inlet.—Although the early run of reds in Cook Inlet was light, the main run appeared in good volume after July 19 and continued strong until August 8. This run was good throughout the Inlet. and was especially heavy between the Kenai and Kasilof Rivers, and in the vicinity of Salamato Beach, between East Foreland and Kenai River. The run of kings was lighter than usual, amounting to only about two-thirds of its normal size. A good escapement of reds was observed on the major spawning grounds, especially in Kasilof and Kenai Rivers, but in Chinik Creek, Cottonwood Creek, and the Kalgin Island stream the escapement was almost a failure. The pinksalmon run was considered fair in most sections, and the seeding of this species as a whole was good, especially in streams south of Anchor

Kodiak area.—The run of reds in the Kodiak area varied considerably in the important red producing sections. The Alitak Bay region had an unusually large run and escapement; in Red River the showing of reds was very poor; and in the Karluk region a normal run occurred and the escapement was good. Kodiak Island as a whole had a light run of pinks, as is generally the case in the even years, although the pink run at Karluk was the largest in many years, and Red River, Alitak Bay, and Uganik Bay had good runs of this species. It is believed that the escapement of pinks was adequate The run and escapement of chums was very for seeding purposes. good generally, but the showing of kings and cohos was only fair.

Chignik.—The runs of all species in the Chignik area were very light this season, but the fact that commercial operators were late in installing traps contributed to the escapement of early runs. Only one trap was operated during the month of June and the red run reached its peak during the last week of that month. of pinks was the weakest since 1931, and the showing of cohos and chums was also poor. Unusually high water in the Chignik River prevented the installation of the weir this season. Stream observations, however, indicated a good escapement of red salmon, although the seeding of other species was poor.

Alaska Peninsula.—The red run in Peninsula waters this season was unusually heavy, although, for unknown reasons, fishing gear on the south side of the Peninsula intercepted a smaller portion of the run than in past years. Pinks and chums were late in arriving but were abundant after July 22, with the exception of a slack period from August 7-10. The run was characterized by the unusually small size of pinks, which in some instances were packed 40 or 50 to a standard case of 48 1 pound-cans. Although not as comprehensive as desired, the survey of spawning areas indicated a rather spotted escapement. It is believed that the Peninsula streams generally were not as well seeded as in other recent years.

Bristol Bay.—The best red-salmon run in the history of the area

Bristol Bay.—The best red-salmon run in the history of the area occurred in Bristol Bay this season, reaching its heaviest volume in the Kvichak-Naknek district and in the Nushagak district. In most sections the run started on July 5, and held up well until the 23d, reaching its peak about the middle of the month. Reds appeared in the Ugashik district at least a week later than in other sections, but the run in this section, as well as in the Egegik district, was weak.

Extensive observations were made, by airplane and boat, of the spawning areas accessible to Bristol Bay red salmon. Of the four important watersheds, the Kvichak-Naknek and Nushagak systems received excellent escapements, the Egegik region was rather poorly seeded, and the Ugashik streams were only thinly populated as usual. Taken as a whole, however, the spawning beds of the Bristol Bay area were well seeded.

GENERAL STATISTICS OF THE FISHERIES

The total number of persons engaged in the fisheries of Alaska in 1938 was 28,084, or 2,247 less than in 1937. Fishery products were valued at \$42,869,726, a decrease of \$8,873,494, or 17 percent, from the value in the preceding year. Of the total amount, 91 percent represented the value of salmon products; 5 percent, herring; 2 percent, halibut; and 2 percent, the value of all other fishery products.

¹ These figures represent the value of the manufactured product. It is estimated that the value of the catch, exclusive of whales, to the fishermen was approximately \$12,040,000. Of this amount, \$9,943,000 was the value of the salmon catch. The round weight of the salmon catch landed by the fishermen was approximately 589,706,000 pounds, and the corresponding figure for herring was approximately 179,735,000 pounds. The cod figures given above do not include the offshore catch from waters adjacent to Alaska, which amounted to 3,065,450 pounds of dry-salted cod and 14,325 pounds of tongues, having a total value of \$130,912, landed at ports of the Pacific Coast States.

SALMON

The commercial catch of salmon in Alaska in 1938 was somewhat smaller than that of the preceding year, although well above the general average, being the fourth largest in the history of the industry. The chief decline was in the catch of pink salmon. The number of reds and cohos, on the other hand, showed a substantial increase over 1937, with the result that there was an increase in the total volume of

salmon products.

Phenomenal runs of red salmon occurred in the Bristol Bay area, and the catch was the largest ever recorded for that region. This unusual abundance was attributed in part to the fact that, during the migration of the runs from the Pacific, comparatively small catches were made on the south side of the Alaska Peninsula, where unfavorable weather conditions hampered fishing operations, particularly in the early part of the season. Although the total number of red salmon taken in central Alaska was somewhat less than in 1937, there was an increase in the pack of this species, indicating a larger average size of the fish. Among the districts which showed a gain in output of canned red salmon were the Kodiak area, Cook Inlet, and Prince William Sound. There was an increase also in the various districts of southeast Alaska, except the west coast of Prince of Wales Island.

Pink salmon were less abundant than in the 2 preceding years in each of the three major districts of Alaska, although the Prince William Sound and Cook Inlet areas showed substantial gains over the production for 1937. An increase in the catch of cohos was rather generally distributed, except that no fall fishing for this species was carried on in the Copper River and Bering River areas. Fewer chum salmon were taken than in 1937, but the volume of products showed an increase. There was a decline in both the catch and pack of king salmon.

The total catch of salmon decreased about 6 percent from that for 1937. By districts, there was a decrease of about 11 percent in southeast Alaska and 14 percent in central Alaska, while in western Alaska

the catch increased 19 percent.

There was a decrease of about 20 percent in the number of fathoms of seines, and an increase of about 11 percent in the number of fathoms of gill nets used in Alaska in 1938, as compared with the previous year.

CATCH AND APPARATUS

The total number of seines used in the salmon industry in 1938 was 801, of which 646 were purse seines and 155 beach seines. The purse seines aggregated 97,310 fathoms of webbing, and the beach seines 14,419 fathoms. The number of gill nets used was 4,711, having a total length of 327,649 fathoms. There were 166 driven and 290 floating traps—a total of 456. This number includes 4 traps in the Chignik district that were installed merely to hold the locations, as well as several traps elsewhere in the Territory, termed "dummy" traps, the catches of which were negligible.

Southeastern Alaska was accredited with 447 seines, or a total of 73,475 fathoms, a decrease of 85 seines and 17,101 fathoms of webbing from the number used in 1937; also with 427 gill nets, aggregating 28,225 fathoms, an increase of 43 nets and 3,265 fathoms of webbing; and with 29 driven and 257 floating traps, a decrease of 3 driven traps

and an increase of 5 floating traps, as compared with the number

operated in 1937.

Corresponding figures for central Alaska show 350 seines, or 37,054 fathoms, as compared with 455 seines, or 46,169 fathoms, in 1937; 2,072 gill nets or 128,745 fathoms, as compared with 1,537 gill nets, or 99,570 fathoms, in 1937; and 137 driven and 33 floating traps, as compared with 138 driven and 31 floating traps in 1937.

In western Alaska 4 seines, or 1,200 fathoms of webbing, were used, a decrease of 4 seines and 1,000 fathoms of webbing from the number operated in 1937. There were 2,212 gill nets used, or an aggregate of 170,679 fathoms, an increase of 148 nets but a decrease of 802 fathoms

of webbing. No traps were operated in this district.

Seines caught 22 percent of the salmon taken in 1938, gill nets 30 percent, and traps 46 percent, while lines and wheels took the remaining 2 percent.

Summary of traps operated in Alaska in 1938, by districts

District	Number	District	Number
Southeast Alaska Central Alaska: Prince William Sound Cook Inlet Kodiak Area	42 62	Central Alaska—Continued. Chignik Area Alaska Peninsula Area Total, Central Alaska Grand total	170

Percentage of salmon caught in each Alaska district, by principal forms of apparatus

	Southeast Alaska		Central Alaska		Western Alaska	
Apparatus	1937	1938	1937	1938	1937	1938
Beines Gill nets Traps Lines Wheels	29 3 65 3	27 2 67 4	39 8 53	32 10 58	4 95	3 96 1

The total catch of salmon in 1938 was 103,022,897, a decrease of 6,092,026, or about 6 percent, from the number taken in 1937. There was a decrease of 4,852,027 in southeast and 5,755,644 in central Alaska, and an increase of 4,515,645 in the western district. By species, the catch of cohos increased 1,062,707 and reds 4,377,102; while the catch of chums decreased 410,521, pinks 10,977,246, and kings 144,068.

Salmon taken in 1938, by apparatus and species, in each geographic section of Alaska

Apparatus and species	Southeast Alaska	Central Alaska	Western Alaska	Total

CANNING

CHANGES IN CANNERIES

Few changes in business organization and operations were reported for 1938 in the Alaska salmon-canning industry. In southeast Alaska the plant of the Demmert Packing Co. at Klawak, which had been idle in the previous year, was taken over and operated by a new concern, the Spencer Packing Corp. The plant of the Nakat Packing Corp. at Hidden Inlet was again in operation, having been rebuilt

since its destruction by fire in the spring of 1937.

In central Alaska the San Juan Fishing & Packing Co. purchased the Drier Bay cannery from the Alaska Pacific Salmon Co. and dismantled it during the season. The cannery of Herbert T. Domenici at Uyak, which was idle in 1937, was taken over and operated by a new organization, the Great Northern Packing Co., Inc. The Shepard Point Packing Co. used its plant at Port Ashton both for salmon canning and for herring operations, but did not operate the cannery at Shepard Point. The Kadiak Fisheries Co. completed construction of its new modern cannery at Port Bailey, about 40 miles northwest of Kodiak, in time for operation in the 1938 season. This plant was built to replace the company's cannery at Kodiak. The Anchor Line Packing Co., formerly operating a floating plant at Seldovia, established and operated a small shore cannery on Kenai River.

At the beginning of the year the Bristol Bay Packing Co. was merged into the Alaska Salmon Co., which operated only the Kvichak River plant during the season. The company's Wood River cannery was used as a saltery, and the second Kvichak River plant, to replace buildings of the Bristol Bay Packing Co. destroyed by fire in 1936,

FIGURE 1.—Typical Alaska salmon cannery.

 ${
m Figure}$ 2.—Completing the cleaning operation, Alaska salmon cannery.

was not completed until after the close of the fishing season. The floating plant La Merced, of the Alaska Southern Packing Co., operated at Uyak Bay, Kodiak Island, during part of the season, but most of its pack was prepared in the Bristol Bay district, operations being carried on at Ships Anchorage in Kvichak Bay.

NEW CANNERIES

Aside from the replacement of certain canneries by new establishments, as mentioned above, there was only one new salmon cannery in Alaska during the season. This was a floating plant operated by Lars Sagen on a small scow at Crescent River, Tuxedna Harbor. Scotty's Packing Co., at Mummy Island, which had previously engaged in the packing of clams and crabs, added canned salmon to its production this season and is included for the first time in the list of salmon canneries.

The Salt Sea Fisheries put up a small pack of salmon, as well as crab meat, at its hand cannery at Tenakee, but this is not included in the list of salmon canneries.

CANNERIES NOT OPERATED

Largely as a result of prolonged labor negotiations in the spring, which resulted in undue delay in preparation for the season's activities, several canneries did not open, and the total number operated was the

smallest for any year since 1933.

Of the canneries in southeast Alaska that were operated in the previous year, the following stood idle in 1938: Berg Packing Co., Ketchikan; Deep Sea Salmon Co., Skowl Arm; Hood Bay Canning Co., Hood Bay; Hydaburg Fisheries, Inc., Hydaburg; New England Fish Co., Chatham; Pyramid Packing Co., Inc., Sitka; and Red Salmon Packers Association, Yakutat. The plant of the Kayler-Otness Co., which was burned down in the fall of 1937, was rebuilt but did not pack salmon in 1938, its operations being confined to crabs and shrimp. The Pacific American Fisheries, Inc., used its plant at Kasaan solely for canning clams that were obtained from the beaches at Massett, B. C.

In central Alaska, plants that were closed for the 1938 season were the King Cove cannery of the Pacific American Fisheries, Inc., the company's catch in this region being put up by P. E. Harris & Co. at False Pass under a joint operating agreement; the Shepard Point cannery of Shepard Point Packing Co.; the Phillips Canning Corporation at Valdez; the Zachar Bay cannery of Shelikof Packing Co., which had been leased to the Kadiak Fisheries Co. in 1937; and the Shearwater Bay plant of Kadiak Fisheries Co., all canning operations of this concern being carried on at its new plant at Port Bailey, which replaces the company's plant at Kodiak. The Kodiak cannery has been discontinued, and all the machinery has been removed. The cannery of A. N. Nilson at Portlock was destroyed by fire during the winter of 1937-38 and was not rebuilt.

The Nushagak and Ugashik plants of the Alaska Packers Association and the Wood River plant of Alaska Salmon Co. were engaged only in the production of pickled salmon in 1938. Other canneries in the western district that had operated in the previous year but were closed in 1938 were the Nushagak and Port Moller plants of Pacific American Fisheries, Inc., and the floating plant of Western Pacific

Packing Co., Egegik River.

The following plants have been dropped from the list of inactive canneries, as they have been dismantled or abandoned and are not likely to be reopened: Alaska Packers Association, Loring, Wrangell, and Kasilof; Alaska Sanitary Packing Co., Cape Fanshaw; Anderson Mercantile Co., Inc., Deep Creek; W. G. Culver, Point McManus; General Fish Co., Ocean Dock, Anchorage; Gustan & Vogel, Point Possession; Libby, McNeill & Libby, Klawak; the Nakat Packing Corporation, Ketchikan; North Coast Packing Co., Ninilchik; Pacific American Fisheries, Inc., Excursion Inlet, Ketchikan, Port Walter, Santa Ana, Chignik, and Unakwik Inlet; Point Possession Fish Co., Point Possession; Redoubt Bay Packing Co., Redoubt Bay: Harvey J. Smith, West Foreland; Spur Fish Corporation, Nikishka Bay; Sunset Packing Co., Otter Creek; John Wik, Kenai; Jake Young, Port Chatham; E. Sandvik, Swansons Creek; and San Juan Fishing & Packing Co., Drier Bay (formerly owned by Alaska Pacific Salmon Co.). The plant of E. Sandvik at Swansons Creek is now being used for pickling salmon.

TOTAL CANNERIES OPERATED

Ninety-eight canneries were operated in Alaska in 1938—39 in southeastern, 41 in central, and 18 in western Alaska—which is a decrease from the previous year of 7 for the southeastern, 3 for the central, and 5 for the western district. The floating canneries International, of the International Packing Co., Memnon, of the Columbia River Packers Association, Inc., and La Merced, of the Alaska Southern Packing Co., Inc., were operated in both central and western Alaska, but each is credited to only one district, the International to central and the other two to western Alaska.

Companies that operated traps only, the catches of which were sold or packed by other companies under joint operating arrangements, have been omitted from the following list, although for a number of years they have been included.

¹ A list of all traps operated in Alaska in 1938 appears on pp. 115 to 121 of this report.

² Primarily a claim cannery.

LOSSES AND DISASTERS

Property losses reported for the Alaska fisheries in 1938 amounted to \$110,235, of which \$45,338 represented the value of some 5,000 cases of canned red salmon lost with a lighter of the Alaska Packers Association in Kvichak Bav, and \$21,000 was the value of a shipment of empty cans lost while being conveyed to the floating cannery of Suryan's, Inc. The remainder consisted chiefly of small boats and

fishing apparatus. The total reported losses in southeast Alaska amounted to \$22,985; those in the central district, \$34,058; and in western Alaska, \$53,192.

Other losses are known to have occurred, of which records are incomplete. One small cannery, that of A. N. Nilson, at Portlock, was destroyed by fire in the winter of 1937-38, but no information is available as to its value.

The most serious disaster was the loss of the purse-seine boat Eidsvold, with the entire crew, somewhere in the vicinity of Dall Island.

Thirty-one lives were lost during the year—14 in southeast, 10 in central, and 7 in western Alaska. In the southeastern district 7 fishermen were drowned, 3 shoresmen and 1 transporter met death in accidents, and 2 shoresmen and 1 transporter died of disease. Two fishermen, 3 shoresmen, and 1 transporter were drowned in central Alaska, 1 fisherman and 2 shoresmen died of disease, and 1 shoresman committed suicide. In western Alaska 2 fishermen were drowned and 1 fisherman, 3 shoresmen and 1 transporter died of disease.

STATISTICS

Ninety-eight canneries were operated in Alaska in 1938, or 15 less than in the previous year. Employment was given to 22,280 persons, as compared with 24,865 in 1937, a decrease of 2,585. White employees decreased 806, natives 536, Chinese 179, Japanese 254, Filipinos 548, Mexicans 243, Puerto Ricans 3, and miscellaneous 44; while Kanakas increased 20 and Negroes 8.

The total pack of canned salmon was 6,806,998 cases, valued at \$36,636,897. This is an increase of 2 percent in quantity but a decrease of about 18 percent in value from the production in 1937, when the pack amounted to 6,669,665 cases, valued at \$44,547,769. Average prices of all species were considerably lower in 1938 than in

the previous year.

The output of canned salmon in southeast Alaska decreased from 2,933,896 cases in 1937 to 2,713,948 cases in 1938, or 7 percent; in central Alaska the decline was from 2,216,359 cases to 2,179,765 cases, or about 2 percent; while in western Alaska the output increased from 1,519,410 cases to 1,913,285 cases, or about 26 percent. By species, in Alaska as a whole, the pack of cohos increased from 137,317 cases in 1937 to 222,321 cases in 1938, or about 62 percent; chums, from 730,832 cases to 786,753 cases, or about 8 percent; and reds from 2,106,669 cases to 2,521,233 cases, or about 20 percent; while the pack of pinks decreased from 3,625,379 cases to 3,232,878 cases, or about 11 percent; and kings from 69,468 cases to 43,813 cases, or about 37 percent.

Details are included in the following tables to show comparison of the 1938 pack with the average for the 5 preceding years, 1933 to 1937, by cases of each species and by districts. Cohos and reds show gains of 17 percent and 23 percent, respectively, over the 5-year average, while chums declined about 4 percent, pinks 7 percent, and kings 13 percent. By districts, the pack in 1938 increased approximately 2 percent over the 5-year average in central Alaska and about 41 percent in the western district, while in southeast Alaska there was a decrease of 12 percent, making a net increase of 3 percent over

the 5-year average for all of Alaska.

PACK IN CERTAIN DISTRICTS

Statistics of the salmon pack are again presented for subdivisions of the three main districts of Alaska, and comparison is made with similar statistics for 1937. Where the pack at a given cannery is made up of fish from more than one district, as in the case of that at certain Cordova canneries packing fish caught both in Prince William Sound and in the Copper River area, or at various plants in southeastern Alaska which draw for their supply on the catch of more than one district, due segregation has been made in order to credit each district with the pack from salmon caught therein. These districts are described as follows:

WESTERN ALASKA

Bristol Bay.—The Bering Sea shore, east and north of the Ugashik River.

Port Moller and Herendeen Bay.—Port Moller, Herendeen Bay, and Nelson Lagoon.

CENTRAL ALASKA

Ikatan-Shumagin Islands.—False Pass, Ikatan Bay, King Cove, and the Shumagin Islands.

Chignik.—Mainland shore from Castle Cape to Cape Kunmik. Kodiak-Afognak Islands.—Kodiak, Spruce, and Raspberry Islands. Cook Inlet.—The shores of Cook Inlet.

Prince William Sound.—Resurrection Bay to Point Whitshed. Copper and Bering Rivers.—Point Whitshed to Bering River.

SOUTHEASTERN ALASKA

Yakutat and Dry Bay.—Yakutat Bay to and including Dry Bay. Icy Strait-Lynn Canal.—West coast of Baranof and Chichagof Islands, the shores of Cross Sound, Icy Strait, Lynn Canal, and

Stephens Passage, south to Taku Harbor.

Chatham Strait-Frederick Sound.—Both shores of Chatham Strait and its bays from Point Augusta to Cape Ommaney, and through Frederick Sound and its bays northward to Taku Harbor, including Kake.

Sumner Strait-Dixon Entrance.—Southward from Petersburg and eastward from Port Beauclerc to Cape Chacon and Dixon Entrance, and including all shores along the mainland and intervening islands from the Stikine River to Portland Canal.

West coast, Prince of Wales Island.—Territory west and south of a line from Cape Chacon to Point Baker and Cape Ommaney.

MILD CURING

Notwithstanding a considerable decrease in the number of troll-caught king salmon in southeast Alaska, the production of mild-cured salmon showed a marked increase over that of the preceding year. The increase was both for kings and for cohos, but chiefly the latter, which made up a larger portion of the pack than for any other year since 1929. The total output was the second largest in the history of the industry, having been exceeded only by the pack in 1927. As usual, the bulk of the product was from southeast Alaska, with a

limited supply also from the western and central districts.

No enumeration of trolling boats was made by the Bureau in 1938, as no patrol vessel was available for this work at the beginning of the season. In respect to the number of fishermen, boats, and lines in southeast Alaska, therefore, the same figures are used as for the preceding year. In order to enable the securing of more accurate data regarding trolling operations in the future, it is the purpose to embody in the Alaska fishery regulations a requirement that before the commencement of commercial fishing each season the name and number of each trolling boat shall be furnished to the Bureau's local representative.

Twenty-one plants were operated in 1938 and 1,753 persons were employed, as compared with 17 plants and 1,605 persons in the previous year. There was also some production of mild-cured salmon

incidental to canning and other operations.

The total output of mild-cured salmon was 6,519,200 pounds, valued at \$1,278,931, an increase of 797,600 pounds in quantity and \$214,587 in value over the production in 1937.

PICKLING

The output of pickled salmon in Alaska showed a marked increase over that for 1937, reaching the highest level for any year since 1926. This increase may be attributed primarily to the excellent runs of red salmon in the Bristol Bay district and to the fact that certain plants there did not engage in canning operations, owing to the undue delay in preparation for the season's activities by reason of unsettled labor conditions. Canneries that were used solely for pickling salmon were the Alaska Salmon Co.'s plant at Wood River, and the Nushagak and Ugashik plants of the Alaska Packers Association. A number of small outfits also engaged in the industry, and some pickled salmon was packed in connection with salmon canning and other branches of the fisheries.

Of the total output, 72 percent was prepared in western Alaska, about 27 percent in the central district, and somewhat less than 1 percent in the southeastern district.

There were 217 persons employed, an increase of 96 over the number reported for 1937. The total output was 1,177,685 pounds, valued at \$122,421, as compared with 765,396 pounds, valued at \$100,550, in the previous year.

FRESH SALMON

As in the previous year, the fresh-salmon business was confined to southeast Alaska, where it was largely incidental to other branches of the fisheries. Three dealers whose chief output was fresh salmon gave employment to 10 white shoresmen. The total products amounted to 3,817,042 pounds, valued at \$291,335, as compared with 3,421,129 pounds, valued at \$292,316, in 1937—an increase of about 12 percent in quantity, but a decrease of about a third of 1 percent in value. The foregoing output includes approximately 35,600 chum salmon, or 308,200 pounds, that were taken in Cholmondeley Sound during the fall season and shipped to a salmon cannery at Anacortes, Wash.

FREEZING

The production of frozen salmon in Alaska, most of which was incidental to mild curing and other branches of the fisheries, was substantially larger in 1938 than in the preceding year. Ninety-nine white shoresmen, not elsewhere recorded, were identified with this industry, receiving wages amounting to \$49,926. Except for a small output incidental to trout operations at Seward, in the central district, the entire production was from southeast Alaska. The total output was 7,185,046 pounds valued at \$530,951, as compared with 5,344,666 pounds valued at \$431,614 in 1937—an increase of 34 percent in quantity and 23 percent in value.

Frozen salmon used as bait in the halibut fishery or as animal feed on fur farms are not included in the above figures but are shown under

miscellaneous salmon products.

DRY-SALTED, DRIED, AND OTHER MISCELLANEOUS SALMON PRODUCTS

An outfit in southeast Alaska and one in the central district reported the dry-salting of salmon. Employment was given to 2 whites and 4 natives, respectively, and the output of dry-salted salmon amounted to 10,500 pounds, valued at \$1,132, in southeast Alaska, and 18,000 pounds, valued at \$500, in central Alaska. Other miscellaneous products in southeast Alaska consisted of 720,652 pounds of frozen salmon for bait, valued at \$7,241; 61,420 pounds of frozen salmon for use as animal feed on fur farms, valued at \$2,500; and 7,300 pounds of salmon eggs, valued at \$365, which were shipped in brine to Seattle for use in specially prepared fish food. An output of 4,025 pounds of dried salmon, valued at \$140, was reported for central Alaska.

Miscellaneous fishery products of the Yukon, Tanana, and Kuskokwim Rivers were 17,300 pounds of dry-salted salmon, valued at \$1,730, and 998,000 pounds of dried salmon, valued at \$71,200. Nine whites and 710 natives engaged in the fishery, and the apparatus used consisted of 238 wheels, 587 gill nets of 14,546 fathoms, 2 dories, and

50 rowboats and skiffs.

BYPRODUCTS

Salmon meal and oil were prepared at a byproducts plant in south-east Alaska, and at a salmon cannery on Larsen Bay, in the central district, in connection with its canning operations. The average number of employees at the former plant was 24 white shoresmen, although approximately three times that number of persons were identified with the industry for varying periods, due to changes in the crews supplied through union hiring halls at different times during the season.

The total production in 1938 was 2,074,000 pounds of fertilizer, valued at \$31,413, and 67,988 gallons of oil, valued at \$15,757, as compared with 1,972,000 pounds of fertilizer, valued at \$29,151, and 78,100 gallons of oil, valued at \$23,956, in 1937—an increase of 5 percent in the output of fertilizer, and a decrease of about 13 percent in the output of oil.

HERRING

As in the previous year, little attention was given to the production of Scotch-cured herring in Alaska in 1938, primarily because of unfavorable market conditions. No pickled herring whatever was reported for southeastern Alaska and the pack in the central district was somewhat curtailed, while in the western district there was a considerable increase, with the result that the total output of Scotch-cured herring in the Territory was slightly larger than that for 1937. Of this output, 552,150 pounds, or 25 percent, came from the western district, while Prince William Sound produced 784,500 pounds and the Kodiak area 849,500 pounds, or 36 percent and 39 percent of the total, respectively.

Herring for bait showed a slight increase, although a shortage during the winter months made it necessary to import a supply of frozen

herring from Prince Rupert.

A sharp curtailment in the production of herring meal and oil in southeast Alaska was partly offset by increases in the Prince William Sound area, but the total output of these products was considerably less than that of the preceding year. There were 17,720,922 pounds of meal and 2,406,822 gallons of oil produced in the Prince William Sound area, or about 55 percent and 53 percent, respectively, of the entire output of meal and oil in Alaska. The Kodiak area accounted for 7,190,194 pounds of meal and 1,215,370 gallons of oil, or 22 percent and 27 percent of the total, respectively, while southeast Alaska produced the remaining 7,279,394 pounds of meal and 900,921 gallons of oil, representing 23 percent and 20 percent of the total of these respective products. As in the preceding year, the figures indicate a relatively high oil content for the herring in the Kodiak area.

It was reported that the herring in the Kodiak area in 1938 arrived later than in the previous year, but finally appeared in large quantities. Most of the fishing in that district was again carried on in the vicinity of Cape Ugat and Uyak Bay.

Nineteen concerns handled herring in southeast Alaska, including 6 cold-storage plants that froze herring for bait and 8 outfits engaged solely in the production of bait herring. Five reduction plants, or 3 less than in the preceding year, were operated in the district, as follows:

Arentsen & Co	Big Port Walter.
Atlas Packing Corporation	
Buchan & Heinen Packing Co	Port Armstrong.
Northwestern Herring Co	Port Conclusion.
Storfold & Grondahl Packing Co	Washington Bay.

In central Alaska nine plants manufactured herring oil and meal, a decrease of one from the number operated in the preceding year. Four of these plants also packed Scotch-cured herring and two produced some bloater stock. In addition, a small quantity of the Scotch-cured product was prepared in connection with salmon pickling in the Kodiak area. W. J. Imlach succeeded the Evans Bay Packing Co. as operator of the plant at Port Benny. The principal herring operators in central Alaska were as follows:

Saltery and reduction plants:

a.
~•
E

Reduction plants:

W. J. Imlach	Port Benny.
Perfection Fisheries, Inc	Thumb Bay.
Shepard Point Packing Co	Port Ashton.
Southwestern Herring, Inc	Iron Creek.
~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~	

Production of pickled herring was reported by four plants in western Alaska, one of which was engaged primarily in the cod fishery. The following were the principal operators in the western district:

Alaska Commercial Co	Unalaska.
Golovin Bay Packing Co	Golovin.
Hovland & Nesskaug	Dutch Harbor.

Studies of the life history and fluctuations in the abundance of the herring populations in Alaska were continued by Edwin H. Dahlgren and two assistants, the work being carried on in southeast Alaska and in the Prince William Sound and Kodiak areas of central Alaska.

### STATISTICAL SUMMARY

There were 940 persons engaged in the herring industry in 1938, as compared with 988 in 1937. The number of plants decreased from 20 to 17. Products of the fishery were valued at \$2,053,084, a decrease of \$838,770, or 29 percent from 1937, when the total value was \$2,891,854. Scotch-cured herring increased from 2,098,040 pounds, valued at \$107,968, to 2,186,150 pounds, valued at \$130,424, or about 4 percent in quantity and about 21 percent in value. Herring for bait increased from 5,238,172 pounds, valued at \$48,816, to 6,143,768 pounds, valued at \$61,802, or 17 percent in quantity and about 27 percent in value. Meal decreased 14 percent in quantity and about 13 percent in value, and oil decreased about 19 percent in quantity and 39 percent in value.

### HALIBUT

The voluntary control of production by the halibut fleet was continued in 1938, with some modifications from the previous program, in an effort to make it more effective in spreading the season's landings and maintaining favorable prices. This system was not entirely successful, and a concentration of landings in the spring was reflected in low price levels.

Regulations of the International Fisheries Commission increased the quotas for areas 2 and 3 by 1,000,000 pounds each. Fishing was discontinued more promptly than in the previous year, however, after the quota was reached. The season opened on April 1, and in areas 1 and 2 it closed at midnight July 29. The final date of clearance for halibut fishing in area 3 was September 29, and fishing in this area and in area 4 closed on October 29.

In addition to the sale of halibut and other fish livers for pharmaceutical purposes, the fishermen in 1938 had a market for halibut and sablefish viscera at 10 cents per pound, this material being used in experiments to determine the feasibility of extracting oils of a high vitamin content. It is understood that the yield of medicinal oil therefrom did not justify the expenditures, however, and that no further contract would be entered into for the purchase of viscera in 1939.

Biological studies of the Pacific halibut were continued by the International Fisheries Commission under the direction of Dr. W. F. Thompson. The schooner *Eagle* was chartered for research work in the Gulf of Alaska in the 1937–38 season.

### STATISTICAL SUMMARY

Seven hundred and twenty-five persons were employed in the Alaska halibut fishery in 1938—an increase of 28 over the number reported for the preceding year; and products, exclusive of livers and viscera, amounted to 13,556,355 pounds, valued at \$890,301. This production represents the total fares of the Alaska halibut fleet, which comprises all American vessels landing more than one-half of their catch in Alaska or British Columbia ports rather than in the States. Landings of halibut, exclusive of livers and viscera, in Alaska totaled 8,296,907 pounds, valued at \$499,472, which include 26,000 pounds valued at \$2,000 landed by Canadian vessels. In 1937 the landings of the Alaska

^{3,622,192} gallons.

¹ 4,523,113 gallons.

fleet were 13,281,681 pounds, valued at \$931,629, and landings in Alaska amounted to 8,705,204 pounds, valued at \$557,911. Fares of the Alaska fleet in 1938, therefore, increased 2 percent in quantity but decreased 4 percent in value from 1937. The landings in Alaska ports in 1938 decreased about 5 percent in quantity and 10 percent in value

from the preceding year.

The amount of halibut livers landed by the Alaska fleet was not reported, but it was stated that there were altogether about 866,000 pounds of halibut, sablefish, "lingcod," and rockfish livers, valued at about \$405,000, landed at Alaska and Pacific coast ports during 1938 by American vessels, as compared with 953,000 pounds, valued at \$449,000, landed by American vessels in 1937. The estimated amount of halibut livers landed in Alaska was 133,000 pounds, valued at \$66,500.

Halibut and sablefish viscera landed by the American fleet amounted to about 983,000 pounds, valued at \$98,000. The estimated amount landed in Alaska was 240,787 pounds, valued at \$24,079. No segregation was made according to species, but as the bulk of the product was halibut viscera, the entire amount is being included in the halibut

statistics.

These statistics were compiled from data collected by the International Fisheries Commission and by agents of the Bureau.

#### COL

Operations in the cod industry were on about the same scale as in other recent years in the Shumagin Islands region and in the vicinity of Unalaska. Twenty-six whites and two natives were reported engaged in the fishery from shore stations, including men aboard the

motor vessels Gloria West (59 tons) and Sitka (50 tons), each of which made an expedition to the westward, the latter for the purpose of experimenting with an otter trawl for the taking of cod. Products amounted to 281,138 pounds of dry-salted cod, valued at \$15,218; 6,678 pounds of stockfish, valued at \$878; and 725 pounds of tongues, valued at \$85—a total of 288,541 pounds, valued at \$16,181, as compared

with 203,327 pounds, valued at \$10,338, in 1937.

Three sailing vessels comprised the Bering Sea fleet, the products of which are not included with the Alaska fisheries output because the vessels operate from and land their fares in ports of the Pacific Coast States. Of these vessels, the Wawona (413 tons) was operated by the Robinson Fisheries Co., and the Sophie Christenson (570 tons) and Charles R. Wilson (328 tons) were operated by the Pacific Coast Codfish Co. The Union Fish Co. did not send any boats north this year.

Products of the offshore fishery were 3,065,450 pounds of dry-salted cod, valued at \$129,572, and 14,325 pounds of tongues, valued at \$1,340—a total of 3,079,775 pounds, valued at \$130,912, as compared with 3,795,923 pounds, valued at \$188,611 in 1937. The offshore fishery employed 104 persons, or 61 less than in the

previous vear.

#### WHALES

The American Pacific Whaling Co. operated only its Akutan station in Alaska during 1938, its other station at Port Hobron, Kodiak Island, standing idle. Of the 136 persons employed during the season, 125 were whites and 11 natives.

There were 5 steam whalers operated, or 1 less than the combined number for the two plants in the preceding year, and 173 whales were taken, consisting of 65 finback, 12 humpback, 33 sulphur bottom,

and 63 sperm whales.

Operations in this industry continued to be controlled by the International Whaling Act and regulations issued thereunder. The regulations of October 9, 1936, were superseded by revised joint regulations of the Secretary of the Treasury and the Secretary of Commerce approved by the President on May 18, 1938. These regulations were again modified in December 1938, giving effect to a supplementary agreement drafted on June 8, 1937, at the International Whaling Conference in London. An important provision of the new agreement was the raising of the minimum-length limit of certain species that may be lawfully taken.

An officer of the Coast Guard was assigned to duty at the Akutan station during the season to enforce the provisions of the Whaling Treaty Act and the regulations. Statistical and biological data were collected by the Bureau and forwarded through the State Department to the International Bureau for Whaling Statistics, Oslo, Norway.

Whale products in 1938 amounted to 304,800 gallons of body oil, valued at \$103,657; 181,900 gallons of sperm oil, valued at \$54,570; 396 tons of meal from meat, valued at \$15,796; and 216 tons of bone meal, valued at \$5,618—a total value of \$179,641, as compared with \$479,121 in 1937.

#### CLAMS

The canning of clams in Alaska in 1938 was centered, as before, in Cordova and vicinity. Notwithstanding the fact that the clam fishery regulations had been modified to permit the taking of an additional 160,000 pounds of razor clams, or a total of 1,200,000 pounds including shells, in the Prince William Sound, Copper River, and Bering River areas during the first 6 months of the year, this limit was reached earlier than in 1937 and the spring season closed on April No change was made in the fall quota of 280,000 pounds, but only limited operations were conducted after activities were resumed on August 16, and the quota was not reached. The total output from this district, therefore, was somewhat less than that of the previous year.

An analysis of the catch in the above-mentioned district indicated that at least 98 percent of the clams were mature, the majority running from 7-9 years of age, with 8-year-olds predominating. Bureau's conservation policy has played an important part in restoring the clam beds to a good condition, and it now appears that the area can provide a larger annual pack if digging is extended to outlying grounds. Modified regulations for the ensuing year, therefore, will place a limitation on the output of certain well-known beds and will increase the limitation on the pack for the district as a whole.

Eleven operators, as follows, engaged in the canning of clams in Cordova and vicinity, this activity in some cases being incidental to the canning of salmon or of crab meat: Arctic Sanitary Packing Co. Blue Sea Packing Co., Buck Canning Co., W. R. Gilbert Co., Inc., Gulf Packing Co., E. A. Haltness, Hawkins Island Packing Co., Pioneer Canneries, Inc., Scotty's Packing Co., Sheep Bay Packing Co., and S. E. Smith Packing Co. Other operators in central Alaska were the Enterprise Sea Food Co., at Ninilchik, and the Sandvik Hand The Sheep Bay Packing Co. and the Sandvik Cannery, at Uganik. Hand Cannery packed butter clams; all other production reported for central Alaska consisted of razor clams

In southeast Alaska the plant of the Nickey Packing Co., in Tongass Narrows, prepared a limited pack of butter clams, and the Pacific American Fisheries, Inc., diverted its salmon cannery at Kasaan to clam-packing operations, the raw product for this purpose being m-

ported from the razor clam beds at Massett, B. C.

A small production of razor clams was prepared also at Izembeck Bay, on the north shore of the Alaska Peninsula, by the Pacific Fisheries & Trading Co., in conjunction with its crab-canning activities.

There were 584 persons employed, of whom 477 were whites, 95 natives, 11 Filipinos, and 1 Japanese. The total production amounted to 40,870 cases containing 1,029,588 pounds (1,015,332 pounds of razor clams and 14,256 pounds of butter clams), valued at \$252,774. This is an increase of 26 percent in quantity and 5 percent in value over the output for 1937, when clam products amounted to 816,942 pounds valued at \$240,392.

#### Products of Alaska clam industry in 1938

¹ Of this number, 9,615 cases, valued at \$57,690, were packed from clams obtained from Massett, B. C.

#### SHRIMP

Two plants in southeast Alaska were engaged primarily in the shrimp business: Alaskan Glacier Sea Food Co., at Petersburg, and Reliance Shrimp Co., at Wrangell. Cold-packed shrimp were also produced at the crab cannery of Dean C. Kayler, at Petersburg. which cannery was erected during the winter to replace that of Kayler-Otness, Inc., destroyed by fire in November 1937. A small production of shrimp was reported also by the Alaskan Glacier Sea Food Co., at Cordova, in conjunction with its crab-canning operations.

There were 141 persons engaged in the industry, of whom 27 were whites, 84 natives, 16 Japanese, 9 Filipinos, and 5 Mexicans. Products consisted of 431,900 pounds of cold-packed shrimp meat, valued at \$167,086; 3,211 pounds of frozen shrimp meat, valued at \$1,284; and 690 pounds of fresh shrimp in shell, valued at \$104—a total of 435,801 pounds, valued at \$168,474. Comparable figures for 1937 show a production of 463,385 pounds, valued at \$164,933.

#### CRABS

During the year 1938, four plants in southeast Alaska and seven in the central district were engaged in the crab fishery. The A R B Packing Co. continued to operate as a separate unit its crab plant at Wrangell, which had formerly belonged to the Boardway Canning Co. Other plants in southeast Alaska were those of Dean C. Kayler, at Petersburg, and the Salt Sea Fisheries, at Tenakee, each of which was built to replace one destroyed by fire in the fall of 1937, and the plant of Oscar H. Wood, at Hoonah.

In addition to the operations carried on at its Cordova plant, the Alaskan Glacier Sea Food Co. packed crab meat at a newly equipped branch plant on Bering River. Engaged in the crab industry in the Cordova region also were the Gulf Packing Co., which packed both clams and salmon; the S. E. Smith Packing Co., primarily a clam cannery; and the Sheep Bay Packing Co.

The canning of king crabs was again carried on by the King Crab Co., at Seldovia. A limited pack of this species was prepared also by the Pacific Fisheries & Trading Co. aboard its floating plant Tondeleyo, which prospected for crabs in the Kodiak area and to the westward along the Alaska Peninsula.

The bulk of the season's output was canned, less than 10 percent of the total volume of crab products being made up of cold-packed

meat and whole crabs in the shell.

There were 420 persons engaged in the industry, of whom 332 were whites, 61 natives, 26 Filipinos, and 1 Mexican. Products consisted of 448,761 pounds of canned crab meat (3,866 cases of 6½-ounce cans, 12,092 cases of ½-pound cans, 296 cases of 13-ounce cans, and 749 cases of 1-pound cans, 48 to the case; 224 cases of 1-pound cans, 90 to the case; and 517 cases of 20-ounce cans, 24 to the case), valued at \$169,480; 2,765 pounds of cold-packed meat, valued at \$1,134; 225 pounds of crab meat in bulk, sold locally, valued at \$90; and 1,029 dozen whole crabs in the shell, valued at \$1,934. Except for 24,312 pounds of king crab (1,013 cases of ½-pound cans), valued at \$9,747, the entire production was of Dungeness crab. The total output of crab products in 1938 was 483,276 pounds, valued at \$172,638, as compared with 711,318 pounds valued at \$276,099 in 1937, a decrease of 32 percent in quantity and 37 percent in value.

## TROUT

The commercial production of Dolly Varden and steelhead trout in the Territory is small and, for the most part, incidental to other branches of the fisheries in southeast Alaska. During the 1938 season, however, 2 white fishermen in the central district were engaged in the industry. The total products were as follows: Dolly Vardens, 52,128 pounds fresh, valued at \$4,712, and 20,395 pounds frozen, valued at \$1,926; steelheads, 334 pounds fresh, valued at \$17, and 5,875 pounds frozen, valued at \$236.

#### MISCELLANEOUS FISHERY PRODUCTS

Fish of minor commercial importance are taken in limited quantities, chiefly in connection with the halibut fishery, and are landed in ports of Alaska and British Columbia and at Seattle. Such products landed in Alaska in 1938 were as follows: Sablefish, 776,825 pounds frozen, valued at \$23,499; 100,364 pounds pickled, valued at \$4,167, and 32,045 pounds of livers, valued at \$11,216; rockfish, 4,376 pounds frozen, valued at \$90, flounders, 150,000 pounds fresh, valued at \$3,750, and 82,145 pounds frozen, valued at \$3,300; "lingcod", 610 pounds fresh, valued at \$10; and "lingcod" and rockfish livers. 1.544 pounds, valued at \$618.

# **FUR-SEAL INDUSTRY**

#### PRIBILOF ISLANDS

#### GENERAL ADMINISTRATIVE WORK

In 1938, 58,364 fur-seal skins were taken at the Pribilof Islands. an increase of 3,184 over the numbers taken in the preceding year. Of the skins obtained on St. Paul Island, 43,867 were removed from the animals by the stripping process and blubbered before curing. The remaining 2,215 skins from that island and the entire take of 12.282 skins from St. George Island were removed by the skinning process.

Delivery was made at Seattle to a representative of the Canadian Government of 8,755 sealskins, representing 15 percent of the season's take selected proportionately from the different sizes and grades, in accordance with provisions of the treaty of July 7, 1911. The remaining 49,609 skins were forwarded to the Fouke Fur Co. at St. Louis, Mo., for processing and sale at public auction. From the proceeds of sale of these skins, payment will be made to Japan of its share of 15 percent of the season's take, due under the fur-seal

The byproducts plant at St. Paul Island produced 30,587 gallons of oil and 178% tons of meal from fur-seal carcasses and blubber. Except for small quantities retained at the Pribilof Islands for use as fox feed, these products were shipped to Seattle, where the oil was sold by competitive bidding and the meal was transferred to the Division of Fish Culture for feeding fish in hatcheries throughout the

country.

In the 1938-39 season there were taken on the Pribilof Islands 1,029 fox pelts, consisting of 219 blue and 5 white pelts from St. Paul Island and 799 blue and 6 white pelts from St. George Island.

Sealing and foxing operations were carried on by Pribilof natives under the direction of the Bureau's staff. Approximately 80 additional natives from the mainland and Aleutian Islands were employed

to assist with fur-seal activities during the summer.

On St. George Island three new cottages and a warehouse were built and concrete foundations were laid for a bunkhouse and for a Construction of a new machine shop was started on St. small shed. Paul Island. Sections of road on both islands were repaired or resurfaced, and improved roads were extended on St. George Island. Additional buildings, including a powerhouse and four overnight

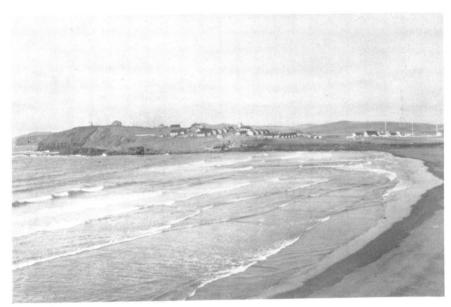

FIGURE 3.—St. Paul Village, St. Paul Island, Alaska.

Figure 4.—Bidarrah unloading supplies from the Bureau of Fisheries vessel *Penguin* at St. George Island, Alaska.

cabins, were erected at the substation for sea-otter patrol in the

western Aleutians.

During the northward migration of the fur seals and while the animals remained in Bering Sea waters, a patrol was maintained by Coast Guard vessels, which also rendered other assistance in the Bureau's work. The Navy Department detailed the U.S.S. Vega to carry the annual shipment of supplies from Seattle to the Pribilof Islands and to bring out the season's take of sealskins.

# TRANSPORTATION OF SUPPLIES

The U. S. S. Vega, of the Navy, sailed from Seattle on July 29 with the annual shipment of supplies for the Pribilof Islands, which aggregated 1,290 tons of general freight, 252,181 board feet of lumber and 540 bundles of shingles for St. Paul Island and 784 tons of freight, 115,427 board feet of lumber and 500 bundles of shingles for St. George Island, a total of 2,074 tons of freight, 367,608 board feet of lumber, and 1,040 bundles of shingles. The vessel arrived at the Islands on August 6.

On the return trip to Seattle, covering the period from August 17 to August 25, the vessel brought out 58,364 sealskins, 168 tons of seal meal, 40 barrels of blubber, 217 empty steel drums, and miscellaneous

freight.

Additional supplies for the Pribilof Islands were shipped during the year on the Penguin.

# POWER VESSEL "PENGUIN"

Five round trips between Seattle and the Pribilof Islands were made by the *Penguin* in 1938, carrying passengers and supplies. In addition, the vessel performed interisland service and made trips to settlements along the Alaska Peninsula and the Aleutian Islands to transport native laborers hired for fur-seal work at the Pribilofs during the summer. Two trips were made to the western Aleutians—one in July and one in September-in connection with the sea-otter patrol. The July trip covered a period of approximately 3 weeks, during part of which time the ship's crew assisted with the construction of a powerhouse and the installation of a power plant and other equipment at the station on Amchitka Island. On the September trip to the westward, freight for the Navy Aerological Station at Kanaga was delivered en route.

A full cargo of freight, chiefly perishable foodstuffs, was carried on each trip from Seattle, and outgoing shipments from the islands included the 1937-38 take of foxskins, transported to Seattle in March, and the fur-seal oil produced at the byproducts plant on St. Paul Island, which was brought out in September and November.

The northbound voyages of the Penguin were as follows: Feb. 19-Mar. 11; May 2-14; June 11-24; Aug. 23-Sept. 5; and Oct. 15-30. Southbound voyages covered the following periods: Mar. 16-29; May 22-June 1; Aug. 3-14; Sept. 23-Oct. 5; and Nov. 2-14. On these voyages transportation was furnished to 76 passengers for the Bureau, including 23 employees of the Fouke Fur Co. who assisted with the season's sealing activities at the islands, and 3 persons connected with the Bureau's salmon patrol and investigations in Alaska. The vessel also transported 21 passengers for the Navy, 5 for the Office of Indian Affairs, 2 for the Coast Guard, 1 for the Bureau of Lighthouses, and 20 unofficial travelers.

The Penguin cruised 29,608 nautical miles during the year.

#### ROADS

St. Paul Island.—No new road work was undertaken on St. Paul Island during the year. About 1½ miles of the Northeast Point plank road around Big Lake was torn up and replaced with a fill of scoria. The Zapadni road was widened for a distance of approximately 800 feet. All other roads were dragged, and where necessary, resurfaced.

St. George Island.—The Staraya Artil road was extended approximately 2,000 feet, to the lake at the foot of the rookery. The Zapadni road was extended about 3,500 feet to a suitable killing ground near the rookery. About 4,000 feet of the Zapadni plank road was torn up and replaced with scoria.

#### BUILDINGS

St. Paul Island.—Construction of a new machine shop was started on St. Paul Island. When fully completed, this building will house all machinery and tools required in a first-class repair shop. There will also be a room for painting, another for overhauling cars, and another for stores. No other major construction work was undertaken on this island.

St. George Island.—Three additional 3-room frame cottages for natives were constructed this season. A warehouse, 20 by 50 feet, was built at Zapadni. This will permit unloading the Penguin during the fall and winter months, when prevailing winds often make the village landing unfavorable for long periods. Concrete foundations were poured for a new bunkhouse for Aleutian workmen and for a small shed to house the hoist used for unloading cargo at the village dock. Considerable repair work on native houses, including reshingling, was undertaken throughout the year.

#### BYPRODUCTS PLANT

The byproducts plant on St. Paul Island was in operation from June 20 to August 3, rendering oil and meal from 31,805 seal carcasses and 7,085 cubic feet, or about 368,420 pounds, of blubbler. Total production for the season amounted to 471 barrels, or 24,252 gallons, of No. 1 oil; 115½ barrels, or 6,335 gallons, of No. 2 oil; and 357,222 pounds of meal. The foregoing quantities in gallons represent averages of 51.49 gallons per barrel of No. 1 oil and 54.85 gallons per barrel of No. 2 oil, as determined from the products sold by weight upon the basis of 7½ pounds to the gallon.

In August the supply vessel Vega brought to Seattle 336,612 pounds of meal, which was turned over to the Division of Fish Culture for use in fish hatcheries throughout the country. The season's output of seal oil was shipped to Seattle on the Penguin—400 barrels on the September voyage, and the remaining 173 barrels in November. As in the past, small quantities of oil and meal were retained at the Pribilof Islands for use as fox feed.

In November, 23,944 gallons of No. 1 fur-seal oil and 5,869.33 gallons of No. 2 oil were sold at Seattle by competitive bidding for \$4,149.19. The No. 1 oil brought 15 cents a gallon and the No. 2 oil 9½ cents a gallon, or decreases of 25 percent and 37 percent, respectively, from the prices obtained for similar grades of oil in 1937. One additional barrel of No. 1 oil, containing 51.49 gallons, was sold to a New York firm at the rate of 15 cents a gallon, for use in experimental processing of sealskins. The total gross receipts for fur-seal oil produced in 1938, therefore, were \$4,156.91.

#### NATIVES

#### CENSUS

On December 31, 1938, the total native population of St. Paul Island was 265, including 12 persons who were temporarily absent from the island. There were seven births and one death during the year. Three natives left the island and settled in Unalaska and one native became a permanent resident on St. George Island.

The census on St. George Island on December 31, 1938, showed a population of 169 natives, including one who moved there from St. Paul Island. There were six births and one death during the year.

The total native population of both islands at the end of 1938 was 434; an increase of eight over the census of the previous year.

#### MEDICAL SERVICE

The customary medical services and facilities were available to Government employees and the natives. One physician was stationed at St. Paul Island and another at St. George Island throughout the year. The general health of the natives was good, and sanitary conditions in the villages were satisfactory.

For the first time in several years a dentist was employed at the islands. He arrived at St. Paul Island on March 12, and during the remainder of the year a great deal of dental work was accomplished there and on St. George Island. Much remained to be done, however, as the teeth of the natives were in very poor condition, and the services of the dentist were continued for an indefinite period.

#### SCHOOLS

Schools for the native children are maintained by the Bureau on St. Paul and St. George Islands, and all children between the ages of 6 and 16 years are required to attend. Two teachers are employed on each island. Instruction is confined to elementary branches, including some manual training and home economics.

The 1937-38 school year began on September 20, 1937, on St. Paul Island and closed on May 6, 1938. School opened on September 13,

1937, on St. George Island and closed on May 13, 1938.

On St. Paul Island there were 12 girls and 26 boys enrolled in the junior school, and 18 girls and 14 boys in the senior school, a total enrollment of 70. On St. George Island 11 girls and 8 boys were in the junior school and 11 girls and 9 boys in the senior school, a total of 39 pupils.

#### SAVINGS ACCOUNTS

A number of the Pribilof Islands natives have savings accounts in the bank of the Washington Loan & Trust Co., Washington, D. C., on which they receive interest compounded semiannually at the rate of 2 percent. The Commissioner of Fisheries, as trustee, had custody during the year of these funds. There follows a summary of the trust account for the year 1938:

On hand Jan. 1, 1938 Interest earned from Jan. 1 to Dec. 31, 1938	\$4, 202. 04 79. 49
TotalWithdrawn by natives	
On hand Dec. 31, 1938	3, 850, 56

The following is an itemized statement of the funds, setting forth the individual accounts:

Funds of the Pribilof Islands natives in the custody of the United States Commissioner of Fisheries, as trustee, December 31, 1938

Kozloff, Marina Lekanof, Tatiana (Merculief)	139. 85 461. 45	Merculief, Elizabeth Merculief, Erena Merculief, George Pankoff, Agrippina	\$74. 84 527. 51 114. 07 214. 53
Lestenkof, Michael Merculief, Alexandra Merculief, Daniel	50, 05	Total	3, 850. 56

#### PAYMENTS FOR TAKING FUR-SEAL SKINS

Natives of the Pribilof Islands are paid for their work in taking sealskins at specified rates per skin. The sealers on each island are divided into classes according to their skill and ability, and the collective earnings are apportioned among them, each worker in a given class receiving an equal share. Small bonuses are paid for special services.

On St. Paul Island the payments to natives in 1938 were at the rate of 60 cents per skin for the 46,082 sealskins taken, or a total of \$27,649.20, and in addition \$180 was paid to 2 foremen and 4 mess attendants.

Natives on St. George Island were paid at the rate of 75 cents per skin, the total in 1938 amounting to \$9,211.50 for the 12,282 sealskins taken, and an additional \$100 was paid to two native foremen.

Details of these payments are shown in the following table:

Payments to Pribilof Islands natives for taking fur-seal skins, calendar year 1938

	St	. Paul Isla	nd	St. George Island

#### PAYMENTS FOR TAKING FOX SKINS

For taking fox skins on the Pribilof Islands in the 1937-38 season the natives were paid at the rate of \$5 per skin. The payments amounted to \$1,230 for the 246 fox skins taken on St. Paul Island and \$3,085 for the 617 skins taken on St. George Island, a total of \$4,315.

#### FUR SEALS

#### KILLING8

In 1938, 58,364 fur seals were killed, of which 46,082 were taken on St. Paul Island and 12,282 on St. George Island. Details in regard to the killings are shown in the following tabulations:

# Seal killings on Pribilof Islands in 1938

#### AGE CLASSES

The age class of a male seal of the Pribilof Islands herd is determined from the length of its body. The classification was derived from measurements of a large number of pups branded in 1912 and killed in subsequent years. The limits of the various age classes are shown in the table following:

## Age classes of male seals, Pribilof Islands

Age	Length	Age	Length
Yearlings 2-year-olds 3-year-olds	Inches Up to 36.75 37 to 40.75 41 to 45.75	4-year-olds. 5-year-olds. 6-year-olds.	Inches 46 to 51.75 52 to 57.78 58 to 63.75

# Ages of seals killed on Pribilof Islands, calendar year 1938

[On basis of classification shown in preceding table]

Age	St. Paul Island	St. George Island	Total
Yearling males 2-year-old males 3-year-old males. 4-year-old males. 5-year-old males. Cows 1	13 1, 431 42, 864 1, 642 2 130	225 11, 276 712	13 1, 656 54, 140 2, 354 2 199
Total	46, 082	12, 282	58, 364

¹ Cows unavoidably and accidentally killed, or found dead.

Some of the seals recorded in the above tabulation as 2-year-olds and 4-year-olds probably were 3-year-olds, as not all male seals of a given age fall within the length limits assigned for the males of that age. As far as possible, the killings in 1938 were confined to 3-year-old males.

#### COMPUTATION OF FUR-SEAL HERD

The computation of the fur-seal herd in 1938 was made by Supt. II. J. Christoffers. As of August 10 the total of all classes was 1,872,-438—a numerical increase of 33,319 over the figures for the preceding year. The detailed report will be found on pages 161 to 168 of this document. The following is a comparative statement of the numerical strength of the various elements of the fur-seal herd in the years 1927 to 1938, inclusive.

General comparison of computations of the seal herd on the Pribilof Islands, 1927 to 1938

#### FOXES

Herds of blue foxes are maintained on St. Paul and St. George Islands which yield several hundred pelts annually. The foxes require very little care, roaming the islands at large and obtaining their food during most of the year from birds, birds' eggs, and marine life along the beaches. In the winter, when the natural supply of food is inadequate, the foxes are fed prepared rations, consisting chiefly of cereals, salted seal meat, and seal oil. During December and January the animals are trapped for their pelts or for marking and releasing as a breeding reserve.

#### TRAPPING SEASON OF 1938-39

In the 1938-39 season there were 1,029 fox pelts taken, of which 1,018 were blue and 11 white. Two hundred and nineteen blue and 5 white pelts were taken on St. Paul Island and 799 blue and 6 white pelts on St. George Island.

There were trapped, marked, and released for breeding stock, 53 male and 44 female foxes on St. Paul Island and 38 males and 49 females on St. George Island. The breeding reserve includes also a considerable number of animals that were not captured during the season.

#### REINDEER

St. Paul Island.—The estimated number of reindeer in the herd on St. Paul Island on September 30, 1938, was 1,943, of which it was estimated that 430 were the young of the season. During the year 103 animals were killed for food. Of this number, 24 were used at the Bureau mess, 50 at the Alcutian mess, 25 by St. Paul Island natives, 6 were transferred to St. George Island, and 4 were not fit for food. The herd was apparently in good condition.

St. George Island.—A count of the reindeer in the herd on St. George Island on September 30, 1938, showed 38 animals, of which 8 were fawns. No reindeer on this island were killed for food during the year.

#### FUR-SEAL SKINS

#### SHIPMENTS

Seven hundred and seventy barrels containing 58,364 fur-seal skins taken on the Pribilof Islands in 1938 were shipped on the U. S. S. Vega and arrived at Seattle on August 25. Forty barrels of blubber, having a gross weight of 19,838 pounds, also were brought out on the Vega and delivered to the Fouke Fur Co., f. o. b. Seattle, for use in the tanning of sealskins.

Delivery of 8,755 sealskins, packed in 114 barrels, was made to a representative of the Canadian Government at Seattle on August 26, in accordance with provisions of the fur-seal treaty. The remaining 49,609 skins were forwarded by freight to the Fouke Fur Co. at St.

Louis, Mo., and arrived there on September 3.

#### SALES

Two public-auction sales of fur-seal skins taken on the Pribilof Islands were held in St. Louis in 1938—on May 2 and October 10, respectively—at which there were sold a total of 44,239 skins for a gross sum of \$941,916. During the year, also, 992 sealskins taken on the Pribilof Islands were disposed of at private sales, under special authorization of the Secretary of Commerce, for a total of \$22,241.68. In the following detailed statements the sales of other sealskins by the Department of Commerce for the account of the Government are included, in order that the records may be complete.

May 2, 1938.—On May 2, 1938, 19,949 Pribilof Islands fur-seal skins, dressed, dyed, and machined, were sold for \$432,622.25. These skins consisted of 7,100 dyed black and 12,849 dyed safari brown.

October 10, 1938.—At the sale on October 10, 24,290 Pribilof Islands fur-seal skins were sold for \$509,293.75. Of these, 24,244 dressed, dyed, and machined, brought \$509,242.75, and 46 raw and partly processed skins brought \$51. In addition, 3 confiscated fur-seal skins were sold raw for \$1.50, making a total of \$509,295.25 for fur-seal skins at this sale.

Special sales.—During the year, 992 Pribilof Islands fur-seal skins were sold under special authorization by the Department for advertising and promotional purposes, the gross sales amounting to \$22,241.68. Of these skins, 563 dyed safari brown brought \$11,617.88; 426 dyed black, \$10,598.29; and 3 raw and partly processed skins,

\$25.51.

Further details in regard to the sales of sealskins by the Department of Commerce for the account of the Government in 1938 are given in the following tables:

# DISPOSITION OF FUR-SEAL SKINS TAKEN ON PRIBILOF ISLANDS

On January 1, 1938, there were on hand 68,498 fur-seal skins taken on the Pribilof Islands. Of these, 68,480 were at St. Louis, Mo., and 18 at Washington. In 1938, 58,364 fur-seal skins were taken on the Pribilof Islands, of which 8,755 were allotted to the Government of the Dominion of Canada as its share of the season's take and the remaining 49,609 were shipped to St. Louis. Of the skins on hand at the beginning of the year, 45,231 were disposed of, leaving 23,267 unsold, which, with the 49,609 from the 1938 take, make a total of 72,876 on hand on December 31, 1938. The following tables show further details in regard to fur-seal skins taken on the Pribilof Islands, as well as details in regard to other fur-seal skins under the control of the Department of Commerce:

# SHIPMENT AND SALE OF FOX SKINS

The 231 blue and 15 white fox skins taken on St. Paul Island and the 616 blue and 1 white fox skins taken on St. George Island in the season of 1937-38 were shipped from the islands on the *Penguin*, sailing on March 15. The vessel reached Seattle on March 29, and the fox skins were forwarded by express to the Department's selling agents at St. Louis, Mo.

At the public auction sale in St. Louis on May 2, 1938, 501 blue and 1 white fox skins of the 1936-37 season's take were sold. The blue pelts brought \$12,423.00, including \$40 for one dressed skin, and the average selling price of the raw blue pelts was \$24.77. The single white pelt was sold dressed for \$15. One fine sivery pelt brought

\$85, which was the maximum price obtained for a single pelt.

On October 10, 1938, there were sold at public auction at St. Louis 423 blue and 16 white fox skins taken on the Pribilof Islands in the 1937-38 season. The blue pelts brought \$10,295.00, an average of \$24.34 per skin; and the white pelts sold for \$216.00, or \$13.50 each. The maximum price obtained was \$72, for a single skin.

## FUR-SEAL PATROL

# UNITED STATES COAST GUARD

Vessels of the Coast Guard were again assigned by the Treasury Department to patrol waters along the route of the Alaska fur seals during their northward migration to the Pribilof Islands. Twelve outters and patrol vessels were instrumental in enforcing the laws and regulations for the protection of fur seals and sea otters in the North Pacific and Bering Sea.

On March 15 the cutter Onondaga began the regular patrol of the Washington coast between the Columbia River entrance and the Strait of Juan de Fuca. Several preliminary cruises were made by

this vessel prior to March 15, and as early as February 15 50 seals were sighted off Willapa Bay. The seal patrol activities of the *Onondaga* were continued until March 26, and were supplemented by frequent cruises of the patrol boat *Atalanta* in the Strait of Juan de Fuca and along the coast of Vancouver Island from March 14 to 31.

On April 1 the cutter *Redwing* relieved the *Onondaga* and continued the patrol northward from Vancouver Island to Dixon Entrance and Clarence Strait. The *Redwing* was relieved on April 20 by the cutter *Haida*, which patrolled the waters from southeast Alaska to Kodiak

until May 5.

Vessels of the Coast Guard which participated in the seal patrol in the North Pacific west of Kodiak, and in Bering Sea, were the patrol boats Alert and Ariadne from April 20 to July 1 and July 10, respectively; the cutter Haida from May 31 to June 29; the cutter Spencer from April 20 to July 31; the cutter Shoshone from June 15 to August 15; the patrol boat Reliance from July 1 to September 10; the cutter Redwing from August 2 to September 10; the patrol boat Cyane from July 5 to September 20; and the cutter Hamilton from July 15 to November 1. The cutter Northland made its regular annual cruise to the Arctic Ocean, patrolling in Bering Sea and adjacent waters from May 20 to September 20.

#### BUREAU OF FISHERIES

The Bureau of Fisheries vessel *Scoter* was assigned to patrol the waters off the coast of Washington, principally in the vicinity of Neah Bay, during the period of sealing operations by the native Indians. The *Scoter* maintained a patrol in this area from March 16 to April 12.

Morris Rafn and William B. Newcomb were detailed to Lapush, Wash., during the scaling season, as special agents of the Bureau to authenticate scalskins and to secure compliance with the treaty provisions which prohibit the use of firearms or motorboats in the taking of fur scals by the aborigines.

#### SEALING PRIVILEGES ACCORDED ABORIGINES

The North Pacific Sealing Convention of July 7, 1911, permits Indians and other aborigines dwelling on the coasts of North America to hunt for seals by primitive methods. In 1938 there were taken and duly authenticated, by officials of the respective Governments, 1,551 fur-seal skins, of which 184 were taken by Indians under the jurisdiction of the United States and 1,367 by Indians of Canada. The details are as follows:

Washington.—A total of 92 sealskins were taken at Lapush and Neah Bay by the Indians of Washington State. Four of these skins were taken from male seals and 88 from females, during the months, of March, April, and May. The skins were authenticated by A. M. Rafn and W. B. Newcomb, special agents of the Bureau, and by Mr. Guy C. Coy, Collector of Customs at Neah Bay, acting as special agent of the Bureau of Fisheries.

Alaska.—Ninety-two sealskins were taken by the natives of Sitka during April and May, and were authenticated by Bureau employees.

Of these skins, 2 were from male and 90 from female seals.

British Columbia.—Indians along the British Columbia coast took 1,367 fur-seal skins in 1938, according to an official report.

FIGURE 5.—Fur-seal harems on Polovina Rookery, St. Paul Island, Alaska.

# JAPANESE SEALSKINS DELIVERED TO THE UNITED STATES

Under the provisions of the fur-seal treaty of 1911, there were allotted to the United States 210 Japanese fur-seal skins, or 10 percent of the number taken by Japan on Robben Island in 1938. These skins were received by the Department's selling agents at St. Louis, Mo., on May 9, 1939.

# SUBSTATION FOR SEA-OTTER PATROL

The Bureau's work for the furtherance of sea-otter investigations and patrol was continued. At the substation established on Amchitka Island in 1937, 4 additional overnight cabins, 8 by 10 feet, were built on the south side of the island at 8-mile intervals. At the camp site in Constantine Harbor a 10 by 16-foot powerhouse was constructed, and a 5-horsepower diesel engine was installed for use as a power plant. Two radio masts were erected on concrete bases, and radio antennae were strung leading to a receiving set and a transmitter. Buildings that had been erected in the previous year were given a coat of paint.

The number of sea otters counted in the vicinity of Amchitka Island in 1938 was considerably less than the estimate for the previous year. Whether the difference was due to an error in the count or to a change in the habits and distribution of the animals was not known. It is anticipated that further light will be thrown upon this problem

by investigations in succeeding years.

# COMPUTATION OF FUR SEALS, PRIBILOF ISLANDS, 1938

# By HARRY J. CHRISTOFFERS

As indicated by the commercial killings, there was a satisfactory increase over the previous year in the number of 3-year-old male fur seals arriving at the Pribilof Islands in the 1938 season. A total of 54,140 3-year-olds were killed, compared with 50,800 in 1937 and 54,890 in 1935. The killings for the past several years, however, do not show a gain commensurate with an average increase of 8 percent in the size of the herd. It is evident, therefore, that during recent years the herd has not been increasing as fast as expected, in view of the increases apparent for the period from 1929 to 1931. dition is probably due in part to insufficient additions to the breeding reserve as a result of continuing sealing operations for several days after July 23. It cannot be the entire cause, however. factors during the life of the seals at sea must have been partly the cause of the large increases from 1929 to 1931, and other unknown factors must have caused a greater loss of life at sea during more recent years. Disease or natural enemies would hardly be expected to increase directly in proportion to the growth of the herd. would not be surprising, therefore, if there should be in any year an abnormally large increase in the number of 3-year-old males available for killing.

The St. George Island killings this year show a remarkable increase over those for the past 2 years, although only slightly more than the

number killed in 1935.

During the last week of the season at St. Paul Island the 3-year-olds continued to come in increasing numbers. The number killed at that time, however, does not show the number which were available; as the rookeries were badly broken up, no seals were driven from the

portions of rookeries having a considerable number of cows.

The experience this year, when a great many 3-year-olds arrived after the rookeries were broken up near the end of the season, indicates the advantage of killing 4-year-olds instead of 3-year-olds. A more definite portion of killable seals could be secured by killing from the 4-year-old class, as these animals arrive much earlier in the season. This would also result in driving a smaller number of cows, a very important point to be considered. Cows do not withstand driving to the same extent as young males. A great many of the cows driven probably die as a result of extreme exhaustion. As previously recommended, therefore, the killing of 4-year-olds still appears advisable, if it should be considered desirable from a commercial standpoint.

Through the courtesy of the Commander of the Bering Sea Patrol and the commanding officer of the Coast Guard cutter Spencer, an airplane made a trip from the village landing to Northeast Point and return. The plane passed over the Polovina rookeries en route and made several trips over the Northeast Point rookeries, for the purpose of ascertaining if it would be practicable to make a pup count by taking pictures from a plane. Motion pictures and still pictures were taken by the Coast Guard, but it appears that the value of such pictures in connection with a census of the fur seals is limited. The black rocks, on which most of the seals are found, are so dark that there is practically no contrast between them and the black pups. In addition, the pups are so small that they cannot be seen from a plane. The seals were not bothered in the least from the noise of the plane.

Adult sea lions, because of their light color, were easily distinguished from the plane, but all of them made a dash for the water when they

heard the plane overhead.

#### BULLS

Insofar as possible, a count was made of all harem and idle bulls. During the counting period at St. Paul Island, harems were increasing and cows were being held in place by the active harem bulls. A couple of days of warm weather, however, caused a break-up of the St. George harems before counts could be made. It was necessary, therefore, to apply to St. George the information obtained at St. Paul, after observ-

ing the actual harem areas occupied.

On certain St. Paul rookeries harem areas were greatly extended, while on others considerably less area was covered than in the previous year. Female seals prefer to crowd together as closely as possible. Therefore, the crowded areas grow faster and contain many more seals per square foot than other portions of the rookery which would appear to be more favorable for their requirements. A cow prefers to enter a large harem rather than to go to a bull with only a few cows or none at all. The favored harems finally become so large that the cows must enter another bull's domain. Then the unfavored one soon accumulates a much larger number.

This year, it will be noted, there was practically no increase in the number of harem bulls and there was a marked reduction in the num-

ber of idle bulls on rookeries. The reduced number of idle bulls was very noticeable from the beginning of the season. Very few surplus bulls took up idle-bull positions, and no trouble was experienced in making an accurate count of the idle bulls. The number recorded for St. Paul Island, therefore, is quite accurate. There appeared to be the usual number of full-grown, strong, and active surplus bulls on the hauling grounds, but they were not interested in taking up idle-Though the shortage of idle bulls was very noticeable, bull positions. it is not necessarily a matter of great importance, as there is no difference between an idle and a surplus bull except in the position he occu-They may change places continually throughout the season. Usually, however, as soon as the idle bulls secure harems, surplus bulls move over from the hauling grounds to become idle bulls, so that there are always about the same number of idle bulls in the rear of the rookeries.

It is interesting to note that 3 bulls branded in 1923 were observed— 1 on Polovina Cliffs rookery and 2 on Reef rookery. All were husky

animals and held large harems in the center of the rookeries.

The decrease in the expected number of harem and idle bulls might possibly be due to the final dying off of the extra males reserved from 1923 to 1932. If so, there is a possibility of a shortage of bulls within the next few years. If the number of harem and idle bulls continues to decrease, it would be advisable each year to make an additional reserve of males.

A shortage of bulls will cause a reduction in the yearly rate of increase of pups. A larger number of surplus bulls can do no harm, except to make it a little more difficult to drive. If previous experience in reserving should be repeated, the increases of killable seals secured through making extra reserves would more than pay for itself within the next 5 years.

The albino bull, first observed in 1935, frequented the idle-bull area back of Reef rookery the greater part of the season. At no time was

he observed with any cows.

#### AVERAGE HAREM

The average harem is computed from the estimated number of cows and harem bulls. This year's figures indicate an increase in the average harem from 43.43 in 1937 to 46.69 in 1938. This increase should not cause any great concern, although a lower average harem would be preferable, as it would show that there were more than sufficient bulls.

It is felt that the more bulls there are on hand the faster the herd will increase. An extra large number of bulls does not now necessarily create a much smaller average harem. It would mean that as the season advances and the harem bulls become exhausted, or at least weaker, their places would be taken by stronger bulls not worn out from harem duties. The present system does not provide for any considerable replacement of harem bulls during the active breeding season.

When man did not interfere and all males grew to maturity, a harem bull would be replaced after a short period of service by a stronger bull. This resulted in a stronger and better race and undoubtedly caused every cow to be properly served, with a resulting

higher birth rate and possibly a smaller mortality rate.

On newly inhabited areas most of the harems were quite large. Below Hutchinsons Hill a single harem, covering a large area, contained at one time over a hundred cows. There were numerous strong, husky bulls without cows a short distance from the harem, but none of them seemed interested in securing any of the cows from this particular harem.

# PUPS AND COWS

The number of pups and cows was determined by applying the average rate of increase secured through actual pup counts made from 1917 to 1922. It is difficult to say whether there was an actual increase of approximately 8 percent, but observations would indicate that this estimate is somewhat high. The harems now cover such large areas that a normal increase in cows would not necessarily be readily observed from year to year, but should be easily discernible over a period of years. From year to year one area may show a large increase or a considerable decrease, as movements are not constant in any particular place.

The number of dead pups did not appear to be proportionately any greater this year than in the past, but the evidence available is not conclusive. To anyone observing the great activity on closely crowded harem areas it would seem highly probable that the death rate of pups is somewhat greater than indicated. The pups in the front portions of the rookeries have in many places a long way to travel to reach the rear of the areas occupied by active harem bulls.

It was quite surprising to note the number of old cows in heat at the end of the season. Many of them had pups recently born. Theoretically the older cows should be bred the first part of the season. If not bred at the proper time they would no doubt come in heat a second time. This would result in the pup being born the following year at a later date than would be normal for the age of the cow.

#### MORTALITY OF SEALS AT SEA

Considering the number of killable seals at the Pribilof Islands in the last few years, as well as general observations regarding the number of older bachelors and surplus bulls on the hauling grounds, it is advisable to increase the mortality rates of pups at sea. Accordingly, there have again been applied the mortality rates for pups which were used in 1925 and which were continued until 1929, when, as a result of additional reserves made in 1923 and 1924, the number of 3-vear-old seals returning to the islands was so great that it was necessary to reduce these mortality rates. If present conditions do not improve, it will be necessary to increase mortality rates for several other ages of male seals and to reduce the percentage increase of pups and cows. There is a strong possibility that the mortality rates increase with the growth of the herd. However, past experience would indicate that the decrease in the rate of growth of the herd is more likely to be directly comparable to the percentage of animals killed. Observations indicated it was advisable to apply the larger mortality rate for pups to all ages up to and including the 5-year-old male class.

Mortality rates for female pups were increased from 40 percent to 45 percent and for males from 40 percent to 50 percent. Experience has shown that for all animals there is a greater death rate among young males than young females. It will be necessary to change mortality rates as new information regarding the life-history of seals

is secured.

#### COMPLETE COMPUTATION

The following summary shows the methods used in computing the number of animals in the Pribilof Islands seal herd in 1938. It will be noted that the mortality rate for female pups was increased from 40 percent to 45 percent and for male pups from 40 percent to 50 percent. In addition, figures carried over from 1937 for yearling females and for all males up to 6 years of age were altered to provide for the newly applied mortality rates from the year the animals were born.

# Complete computation of fur seals, Pribilof Islands, as of August 10, 1938

Class	St. Paul Island	St. George Island	Total

6-year-old males, Aug. 10, 1938	14, 854	2, 415	17, 269

¹ It was found necessary to apply mortality rates of 45 percent for female pups and 50 percent for male pups, instead of 40 percent in each case, as formerly. Adjustments were made in the figures for 1937, therefore, to take care of these increased mortality rates for female pups and yearlings, and for males up to and including 5 years of age.

^{*} Estimates have been worked out, insofar as possible, to show approximately the number of seals of each class which should be credited to each island. The seals, however, do not haul out in accordance with figures given. Seals born on either island frequent the other island. They travel promiscuously between the two islands and haul out on either one. The total for both islands, however, is approximately correct.

## BUREAU OF FISHERIES

CHARLES E. JACKSON, Acting Commissioner

Administrative Report No. 37

# FISHERY INDUSTRIES OF THE UNITED STATES 1938

By R. H. FIEDLER

APPENDIX III TO REPORT OF COMMISSIONER OF FISHERIES
FOR THE FISCAL YEAR 1939

UNITED STATES
GOVERNMENT PRINTING OFFICE
WASHINGTON: 1940

#### ADMINISTRATIVE REPORT SERIES

Since the beginning of the Administrative Report Series, considerable confusion has arisen concerning the system of numbering the separates composing it. Inasmuch as the Reports of the Divisions vary in order from year to year, many have found their designations as "Appendix No. I, II, III, or IV" very confusing. To relieve this, it has been decided to number them as "Administrative Report No. —" Inasmuch as 20 separates had already been printed in this series before starting the numbers, it was deemed advisable to begin the numbering with Administrative Report No. 21. Of course, numbers cannot be printed on those already off the press, but for the information of those who wish to know what the first 25 were, they are numbered for filing purposes as follows:

1. Report, Commissioner of Fisheries, 1931.

No. 2. Alaska Fishery and Fur-Seal Industries, 1930.

No. 3. Fishery Industries of the United States, 1930.

No.

4. Progress in Biological Inquiries, 1930.5. Propagation and Distribution of Food Fishes, 1931. No.

No.

No.

 Report, Commissioner of Fisheries, 1932.
 Alaska Fishery and Fur-Scal Industries, 1931.
 Fishery Industries of the United States, 1931. No.

9. Progress in Biological Inquiries, 1931.

Propagation and Distribution of Food Fishes, 1932. No. 10.

No. 11. Alaska Fishery and Fur-Seal Industries, 1932.

No. 12. Progress in Biological Inquiries, 1932. No. 13.

Fishery Industries of the United States, 1932. Propagation and Distribution of Food Fishes, 1933. No. 14.

Fishery Industries of the United States, 1933. No. 15.

No. 16. Alaska Fishery and Fur-Seal Industries, 1933.

No. 17. Progress in Biological Inquiries, 1933.

No. 18. Propagation and Distribution of Food Fishes, 1934.

Alaska Fishery and Fur-Seal Industries, 1934.

No. 19. No. 20. Fishery Industries of the United States, 1934.

No. 21. Progress in Biological Inquiries, 1934. No. 22. Propagation and Distribution of Food Fishes, 1935.

No. 23. Alaska Fishery and Fur-Seal Industries, 1935.

No. 24. Fishery Industries of the United States, 1935.

No. 25. Propagation and Distribution of Food Fishes, 1936.

Note that the last Commissioner's Report was for 1932. Since then its place has been taken by a reprint from the report of the Secretary of Commerce under the title "Bureau of Fisheries." Inasmuch as it is no longer a Bureau publication, it is not numbered; but it will be supplied to any who request the Report of the Commissioner for any year since 1932.

#### FOREWORD

This report constitutes a summary of the activities of the Division of Fisherv Industries, as well as a review of the fishery statistics collected by the Division during the past year. As its name indicates, this Division of the Bureau is concerned with the activities and welfare of the commercial fisheries and fishery industries and the fishermen and shoresmen engaged therein; the fish canning and preserving industries; and the trade in fishery products. Its functions include the conduct of studies or activities: (1) To determine the extent and magnitude of our aquatic resources and the commercial importance of our fishery industries; (2) to learn the economic condition of fishermen and shoresmen engaged in the fishery industry, their place in the national economy, and what measures can be taken to improve their well-being; (3) to determine the character, utility, and effectiveness of different forms of fishing apparatus and vessels, suggest improvements therein, and discourage the use of those forms which are unnecessarily destructive or unprofitable; (4) to learn the effect of fishing on the supply of fish and suggest measures to promote orderly and sustained production; (5) to study and develop fisheries for hitherto unutilized fishes; (6) to investigate the preservation of fishery products, suggest improved methods, and discourage wasteful practices in this field; (7) to ascertain what use can be made of aquatic products not now utilized to economic advantage; (8) to inquire into the nutritive value of aquatic foods for man and his domestic animals. and promote the consumption of these foods; (9) to ascertain the means and methods of transporting fishery products on land and sea and recommend economical practices; (10) to inquire into the condition and extent of the wholesale and retail trade in fishery products and promote the more orderly marketing of our fishery harvest; (11) to introduce useful foreign methods or processes of capture, preservation. utilization, or marketing fishery products; (12) to handle matters relative to the administration of the act which authorizes cooperative associations of producers of aquatic products; and (13) to conduct the fishery market news service authorized by act of Congress in 1937.

Results of the various technological, economic, and marketing investigations carried on by the Division are published in separate documents as each project is completed, and a brief résumé of each current project is contained in this report. Information obtained from statistical surveys is published in part 2 of this report, which includes all the detailed statistical information that has become available since issuance of the previous report 2 together with such summarized statements and interpretations of the statistics as are deemed

significant and useful.

# Part 1. OPERATIONS OF THE DIVISION COOPERATION WITH OTHER FEDERAL AGENCIES

It has been the established policy of the Bureau of Fisheries and of this Division to cooperate with other Federal agencies wherever the activities are such that mutual information can be exchanged with advantage or where, by working cooperatively, the results of such

¹ Fishery Industries of the United States, 1937, by R. H. Fiedler: Appendix III to the Report of the U. S. Commissioner of Fisheries for 1938, pp. 151-460.

mutual work may be furthered or its ends made more effective and

Thus, the technologists of this Division gave courses in canning fishery products to State Extension Service workers at the request of and with the cooperation of the Extension Service of the United States Department of Agriculture. Demonstrations and practical instruction on other related subjects, pertaining to the preservation of fishery products and a better utilization of the excellent food value of fish, were given to State Extension Service workers through and with the cooperation of the Extension Service of the United States Department of Agriculture. In some cases, students or State Extension Service workers were detailed to the Bureau's laboratories in Washington, D. C., for instruction, and in other cases one of our technologists visited some of the States for this purpose.

Cooperation was also given by members of our technological staff to chemists and bacteriologists of the Food and Drug Administration, United States Department of Agriculture, at various times in connection with the development and application of tests or methods of determining the quality and constituents of various fishery products.

On several occasions members of the Division's economic and marketing staff cooperated with the Department of Labor in holding conferences with fishermen's unions and associations to settle disputes. The Department of Labor, through its Employment Service, also gave considerable aid to the Division in selecting personnel for the

conduct of the Division's survey of retail fish markets.

The Division also has worked with various Federal agencies in obtaining statistical data on our fisheries. In a cooperative arrangement, the Bureau of Agricultural Economics, Department of Agriculture, furnished statistics on the volume of cold-storage holdings of fish and quantities frozen, and the health authorities in Washington, D. C., assisted in obtaining data on the volume of fish handled at the Municipal Fish Wharf and Market in this city. Cooperation was accorded the Bureau of the Census in obtaining for that Bureau figures on the volume of the quarterly production and holdings of fish oils in the United States.

In addition to the specifically enumerated instances of cooperation with other Federal agencies cited above, which are on a continuing basis or were of a more detailed nature, it should be stated that a very close relationship exists between this Division and many of those Federal agencies whose duties require an interest in fish in particular, foodstuffs or feedstuffs in general, or in various marine activities. The staff of the Division is in almost daily contact with some one or more of these Federal agencies in the exchange of information of inestimable value to the scientific work of the Federal establishment.

# COOPERATION WITH STATE AGENCIES

The Division has continued to encourage cooperative relations with State institutions and agencies in the conduct of researches and investigations of mutual interest. This policy has resulted in expanded programs and decreased costs. During 1938 the following cooperative investigations with various States were conducted:

At Washington State College, Pullman, Wash., the Seattle technological laboratory staff of this Division worked with Dr. J. S. Carver

in connection with tests on the feeding of fish oils and fish meals to poultry. Our Seattle technological laboratory staff also continued its close cooperative relation with members of the faculty and staff of the

University of Washington, Seattle, Wash., as in past years.

The University of Maryland and the Maryland State Agricultural Experiment Station, College Park Md., continued their excellent cooperative relations with our College Park technological laboratory staff. Additional free space for the Bureau's laboratories was provided by the University of Maryland for the expanded technological work of the Bureau at that place. For example the use of another room was donated to the Division for the establishment of a new bacteriological laboratory in the Horticultural Building of the Uni-The various departments of animal husbandry of the Maryland State Agricultural Experiment Station continued their cooperation in the conduct of feeding tests of fishery byproducts in the rations of farm animals. The members of the staffs of these two institutions who have worked closely with our College Park technological staff are Dr. L. B. Broughton, Head of the Chemistry Department; Dr. W. C. Supplee and Mr. L. E. Bopst of the Chemistry Department; Dr. L. H. James, Head of the Department of Bacteriology; and Prof. M. H. Berry of the Dairy Department. These various cooperative studies are described in greater detail elsewhere in this report.

As discussed in the 1937 report, the Bureau's technologists continued their cooperation with the Virginia State Division of Markets in extending and improving State marketing grades for fishery products

sold in that State.

The Bureau's economists and marketing specialists are working in close cooperation with the Division of Markets of the Virginia State Department of Agriculture and Immigration in connection with the survey of retail fish markets which is discussed elsewhere in this report. The Division of Markets furnished the services of a man who surveyed the retail fish markets in Harrisonburg, Staunton, Lexington, Roanoke, Lynchburg, and Charlottesville. These markets could not otherwise have been covered.

In the conduct of its statistical research work the Bureau obtains unusual cooperation from various States. The statistical surveys of the fisheries in the States bordering on the Great Lakes, in the Pacific Coast States, and in New York, Maryland, and Virginia have been greatly facilitated by the cooperation obtained from the fishery agencies in these States. With this aid it is now necessary for the Bureau to conduct only partial surveys in these States to supplement the data available from the fishery agencies. A comprehensive system for the collection of fishery statistics in the State of Maine is now being developed by the State of Maine in cooperation with members of the Bureau's staff.

In addition, in nearly every other State where commercial fishing is prosecuted, some type of cooperation in its statistical work is rendered the Bureau by the State fishery agencies or other organizations. This makes it possible for the Bureau to make statistical surveys of a greater portion of our fishery industries than otherwise would be

possible.

## COOPERATION WITH FISHERY ADVISORY COMMITTEE

The Division of Fishery Industries offered its fullest assistance during the year to the Fishery Advisory Committee for the Department of Commerce. Facts and figures upon the scope and conditions of the fisheries are not readily apparent except through the data collected and compiled by the Bureau of Fisheries and for this reason the success of the meetings of this Committee is partially reliant upon cooperative assistance of the Bureau's staff.

During the fiscal year the Fishery Advisory Committee held two official meetings. The first of these occurred on October 5, 1938, in Boston. This meeting was held in conjunction with the National Fishery Convention which was held in Boston during the first week of October. The division contributed to the deliberations of this meeting, furnishing summaries of activities and problems as well as

assisting in the program of the meeting and in its publicity.

Assistance was also furnished the Committee in its second meeting, which was held on January 30 and 31, 1939, in the Department of Commerce Building in Washington. The full technical personnel of the Washington area was made available for consultation at this meeting. An outline of fishery problems and the Bureau's activities in relation thereto provided the foundation of the Committee's program.

The meetings resulted in the passage of resolutions, concerning the operations of the Division of Fishery Industries, which endorsed the enlargement of the Market News Service; recommended a thorough study of retail fish marketing; and urged the establishment of an extension service and the making of quality and consumption studies

by the Bureau.

# COOPERATIVE PAN-AMERICAN FISHERY RESEARCH

At the request of Dr. Ernest Gruening, Director of the Division of Territories and Island Possessions of the Department of the Interior, the writer was detailed as adviser on fishery matters to accompany the President's Educational Commission to Puerto Rico. The commission conducted a study of the University of Puerto Rico with the view of developing this university into a Pan-American institution. This project was recommended to President Roosevelt by his Committee on Cooperation with Latin America, and was approved by him. The commission was headed by President Isaiah Bowman of The Johns Hopkins University.

Our neighbors to the south are constantly asking us for assistance in the field of fisheries. In view of this, it appeared desirable to explore the place and need for a school of fisheries or fishery research laboratory at the proposed Pan-American institution in Puerto Rico which could serve as a focal point for fishery education to students from the

Americas and the West Indies.

The development of a fishery school or research laboratory also would round out a program of scientific cooperation with Latin America which already has had its beginnings in a School of Tropical Medicine. This school is conducted under the joint auspices of the University of Puerto Rico and Columbia University. Plans are also under way for the development of graduate schools of tropical forestry and tropical agriculture.

The commission left New York City for Puerto Rico on April 6 and returned April 24, 1939. Its findings and recommendations have been reported to the President.

#### EXHIBITS AT EXPOSITIONS

During 1938 the Division of Fishery Industries finished arrangements for a Bureau of Fisheries display for the Pan-American Exposition at Tampa, Fla., and planned the participation of the Bureau in the "theme" exhibits for the New York World's Fair, 1939. The display at Tampa consisted of a diorama of the sponge-fishing industry. At the New York Fair the Bureau was represented in the following dioramas: Conservation, Food, Industry, Recreation, and Territories. Displays also were shipped to San Francisco for the use of Fair authorities at that city in the Golden Gate International Exposition. These consisted of illuminated panels depicting the migration of the Alaska salmon in the Pacific Ocean and the American and European eels in the Atlantic Ocean. The Bureau also was represented in the Conservation theme at this Fair.

The publicity attendant upon the public showing of displays depicting the Bureau's activities and operations in the fishery industries is recognized as an important factor in the public relations of the

Bureau of Fisheries.

#### ECONOMIC AND MARKETING INVESTIGATIONS

There is a constant demand upon the Division of Fishery Industries to conduct economic studies of the commercial fisheries, including investigations having application to the various functions of marketing fishery commodities. It has been possible to undertake only a limited program of long-time or continuing studies of this kind with available personnel and funds during recent years. However, as is customary each year, many short-time economic and marketing studies were made in order to satisfy the urgent demands placed upon the Division. Some of these studies are conducted preliminary to or closely associated with administrative activities of the Bureau and, consequently, they are frequently not published. Some of the economic and marketing studies which were made during the past year are discussed briefly in the following paragraphs.

#### SURPLUS-FISH SITUATION

As a result of the legislation incorporated in Public Act 542, which was approved on May 25, 1938, the Federal Surplus Commodities Corporation, during the latter part of the fiscal year 1938, purchased 3,595,000 pounds of fish and fish products at a commodity cost of about \$265,000. These purchases consisted largely of pollock, haddock, cod, mackerel, blue runner, hake, and squeteagues or "sea trout." It will be recalled that 12,059,000 pounds of fishery products were purchased, at a commodity cost of \$597,000, during the latter part of the fiscal year 1937 under similar authority. These costs do not include handling and transportation.

Fishery commodities purchased by the Federal Surplus Commodities Corporation were diverted from the normal channels of trade and commerce by their distribution through Federal, State, and private

relief agencies.

A study of the situation with respect to surplus fish was made by the staff of the Division during April and May 1939. The findings of this study were presented by the writer on May 31, 1939, before the Committee on Merchant Marine and Fisheries of the House of Representatives in connection with the deliberations of that Committee on H. R. 5025 and 5681.

The former of these bills had for its purpose the provision of temporary measures for the further purchase of fishery products for distribution to relief clients, while H. R. 5681 was designed to furnish permanent provision for the removal of surplus fishery commodities

from the normal channels of trade and commerce.

The study made in the Division developed the following informa-

Frozen and cured fish.—The holdings of frozen fishery products in cold-storage warehouses in the United States on April 15, 1939, amounted to 29,744,000 pounds, compared with 37,367,000 pounds on the same date the previous year. This is 882,000 pounds in excess of the normal or 5-year average of the holdings as of April 15, which amounted to 28,862,000 pounds.

The excess holdings as of April 15, 1939, over the 5-year average for this date consisted principally of shellfish, largely shrimp originating from the South Atlantic and Gulf coast; shad from the Atlantic coast; sablefish from the Pacific coast; and various fresh-water fish

from the Great Lakes.

On April 15, 1939 the cold-storage holdings of cured herring amounted to 15,670,000 pounds, compared with 15,082,000 pounds on the same date in 1938 and the 5-year average of 12,229,000 pounds as of April 15.

Cold-storage holdings of mild-cured salmon on April 15, 1939, amounted to 3,529,000 pounds, compared with 2,719,000 pounds on the same date a year ago and the 5-year average of 3,116,000 pounds

as of April 15.

Canned fish.—Holdings of canned salmon in the hands of packers, according to a report of the Association of Pacific Fisheries, Seattle, Wash., amounted to 2,032,591 standard cases of 48 1-pound cans per case on February 28, 1939. This is a decrease of 1,396,000 cases, or 67,000,000 pounds, as compared with the holdings on the same date

the previous year.

Data obtained by telegram from members of the industry showed that holdings of canned tuna on March 15, 1939, amounted to 9,600,000 pounds, or approximately 6,000,000 pounds less than a year ago, while those of California sardines aggregated 7,900,000 pounds, or 3,100,000 pounds more than on the same date the previous year. holdings of canned shrimp amounted to 4,500,000 pounds which were almost identical with the holdings a year ago, and those of canned oysters were 2,600,000 pounds, or 800,000 pounds greater than in the preceding year. It is reported that there were no stocks of Maine sardines in packers hands on March 15 this year, but last year holdings of this product totaled about 8,000,000 pounds.

Summary.—The holdings in the spring of 1939 of all of the types of edible fishery products outlined above aggregated about 172,000,000 pounds compared with 256,000,000 pounds as of comparable dates a year ago. The holdings this year represented an excess of about 5,600,000 pounds over normal holdings for this time of the year.

### SURVEY OF RETAIL MARKETING OF FISH AND SHELLFISH

Following an intensive preliminary study to determine the most efficient procedure and coverage, a survey of retail marketing of fish and shellfish was undertaken in March 1939 under the direction of Ralph Russell, Associate Fishery Economist, to include about 50 representative cities east of the Mississippi River.

The annual domestic per capita consumption of fish amounts to only 13 pounds; less than that of most of the important countries of the world. This low consumption not only curbs the potential growth of our commercial fisheries but also is evidence of the restricted volume of these healthful foods in the average diet. Recent studies indicate wide variations in the consumption of fish among various cities as well as among the various social and economic groups of residents of these cities.

It is the purpose of this survey to study the conditions under which fish are sold in retail markets. To accomplish this, the Bureau's investigators are interviewing a large number of dealers representing all segments of the retail trade to obtain information on retail methods, equipment used, prevalence and nature of advertising, consumer preference and response, location of retail outlets, and characteristic as well as unusual merchandising practices and selling methods. The field work of this survey will continue until about the end of June 1939, after which the results of the survey will be tabulated and analyzed to determine the factors which lead to the most favorable response from the public and to establish criteria which may guide retailers toward those practices which are most successful or promising. It is expected that one or more reports will be published following the completion of this work.

#### COMMERCIAL FISHERIES OF THE WORLD

The world's annual catch of fishery products, based on the most recent available data, amounts to about 33,600,000,000 pounds, valued at \$740,000,000. The United States, including Alaska, with a catch valued at \$93,000,000, leads the countries of the world in the annual value of its yield. Japan's annual catch, valued at \$87,000,000, ranks second. Other countries, the annual catch of which exceeds \$50,000,-000 in value are, in order of their importance, Union of Soviet Socialist Republics; England, including Scotland, Northern Ireland, and Wales: China; and France. Japan, with a catch of 6,600,000,000 pounds, leads in the annual volume of the catch among the countries of the world. Following is the United States with a catch aggregating 4,800,000,000 pounds. Other countries whose annual catches exceed 1,500,000,000 pounds are, in order of their importance, Union of Soviet Socialist Republics; China; England, including Scotland, Northern Ireland, and Wales; Norway; and Germany.

#### THE ROSEFISH FISHERY OF NEW ENGLAND

The rosefish or "redfish" fishery of New England experienced another good year in 1938 from the standpoint of total yield, although the average value to the fisherman decreased to 1.2 cents per pound from

1.5 cents in the previous year. Landings of this species at the ports of Boston and Gloucester, Mass., and Portland, Maine, aggregated 64,700,000 pounds in 1938 as compared with 58,300,000 pounds in 1937, and the all-time high of 66,600,000 pounds in 1936. It will be recalled that prior to the intensive exploitation of this fishery in 1935 the rosefish was of little importance as a commercial species. The entire landings at the three above-mentioned principal New England

ports amounted to only 57,000 pounds in 1932.

During the 4 years beginning in 1935, in which this fishery has been one of importance, Boston has received about 67 percent of the landings, Gloucester 32 percent, and Portland 1 percent. However, during these 4 years the relative importance of the individual ports in the receipts of rosefish has undergone considerable change. The landings at Boston, while amounting to 49,400,000 pounds in 1936, decreased to 34,100,000 pounds in 1938. The landings at Gloucester amounted to 17,000,000 pounds in each of the years 1936 and 1937 but increased sharply to 29,400,000 pounds in 1938. The receipts of this species by vessels at Portland have increased from 70,000 pounds in 1935 to 1,150,000 pounds in 1938.

While rosefish are taken widely throughout the fishing banks of the North Atlantic, the Western Side of South Channel alone contributed 35 percent of the landings at these three New England ports during 1937. Other fishing areas of especial importance as contributors to the landings at these three ports were as follows: Southern Nova Scotia 21 percent, Brown's Bank 20 percent, Eastern Side South Channel 11 percent, Inner Grounds 5 percent, and Western Nova Scotia 3 percent.

Virtually the entire catch of rosefish is made by otter trawls.

# COD FISHERIES OFF THE EAST COAST OF NORTH AMERICA

The average annual catch of cod off the East coast of North America for the 10-year period from 1926 to 1935, inclusive, amounted to 1,108,000,000 pounds, as compared with an annual average of 1,169,-000,000 pounds for the preceding 10-year period, according to a report prepared by Edward A. Power, Associate Statistician and the writer, for the use of the North American Council on Fishery Investigations. The present study brings up to date Fisheries Document No. 1034 entitled "Statistics of the Catch of Cod Off the East Coast of North America to 1926," by Oscar E. Sette, which includes available data on the cod fishery prior to 1927. In 1935, the most recent year for which complete statistics are available, the catch of cod in this region amounted to 1,109,000,000 pounds. The cod fisheries off the East amounted to 1,109,000,000 pounds. coast of North America are prosecuted by the nationals of no less than five countries. The most important among these, with respect to the annual volume of fish taken, is Newfoundland, the catch of which in the years from 1931 to 1935, inclusive, averaged 495,000,000 pounds. Following in order were Canada, which produced an average of 192,000,000 pounds annually during the same period; France, 127,-000,000 pounds; United States, 109,000,000 pounds; and Portugal, 40,000,000 pounds.

# SOURCES AND SUPPLIES OF STURGEON

Imports of sturgeon into the United States have been consistently decreasing in recent years. In 1931 receipts of sturgeon from foreign countries amounted to 3,435,000 pounds, but decreased to 1,744,000 pounds in 1934 and 1,184,000 pounds in 1938. This decline in imports is reflected principally in receipts from the Soviet Union which is the principal source of supply. Where imports from the Soviet Union amounted to 1,605,000 pounds in 1934, they decreased to 750,000

pounds in 1938.

Contrasted with the decline in receipts of sturgeon from the Soviet Union are the steadily increasing imports from Canada. Such imports amounted to only 124,000 pounds in 1934, but had increased to 353,000 pounds in 1938. Receipts from Canada were augmented during the latter part of 1938 by the development of a new source of supply in the Albany River in northern Ontario. According to a report from Warwick Perkins, American Consul at Toronto, Canada, the capture of sturgeon in this river in the past has been incidental to fisheries for other species, but, due to the high unit value of sturgeon, it has been found profitable to prosecute a fishery specifically for this fish, transporting the catch by aircraft to Nakina for transshipment on the Canadian National Railways.

It is of interest to observe that imported sturgeon furnishes our principal supply, since the domestic annual catch has averaged less

than 300,000 pounds in recent years.

#### STATISTICAL INVESTIGATIONS

Fishery statistics are collected by the Bureau to serve two principal purposes—biological and economic. For this reason the Bureau plans its statistical surveys to obtain comprehensive data for furnishing a complete and reliable picture of the condition and trend of the fisheries. The collection and compilation of the great mass of data necessary involves many problems. The fisheries are broad in scope, including over 160 varieties of aquatic products which enter into commercial production. These, many of which are migratory, are taken by a great variety of types of gear in areas along our seacoast and in our interior lakes and streams. If the biological aspect is to be served, complete annual statistics are needed on each of these phases in every section. If the economic aspect is to be served, statistics are needed not only on the phases listed above relative to the biological aspect, but also on the price structure, the processing function, and on marketing and distributing.

It is essential that statistics on these latter phases of the industry be collected and published as soon as possible after the close of the business transactions in order that they may be of maximum value to

the fishery industry and other interested parties.

#### BIOLOGICAL ASPECT

The biological aspect must consider two problems—the conservation and sustained supply of the resource, and the prediction of future trends or yields. Since the fisheries are usually prosecuted in areas not under private ownership, the problem of the conservation of these fisheries is of national concern. It is important that close watch be kept of the condition of the various fisheries to detect depletion so that remedial measures can be promulgated timely and wisely. For this reason it is imperative that current statistical data be obtained on the yield of our fisheries.

These statistics furnish the biologist with the background upon which to base his prediction of future trends and yields. This he does by coupling the statistical data with studies of the life history of the species. Difficulty is experienced in making these predictions because the supply (population) of the species cannot be seen, as is the case with farm animals or crops. The more complete and more reliable the statistics on yield are, the better foundation the biologist has for conducting his studies. The Bureau, therefore, aims to obtain a complete picture of each individual fishery to further these biological studies. ECONOMIC ASPECT

When the fishery has been conserved, and trends and yields of the fishery have been predicted, the problem still remains of supplying the fishery trade with the information so essential to the conduct of its business activities. In these days of increased competition the very existence of the fishery industry must depend upon reliable economic and statistical information. Such material has been especially valuable during the past few years, when it has been used in national planning. The Bureau endeavors to make its statistical surveys so complete that the industry and the various governmental organizations may turn to it for reliable fishery statistics.

## SURVEYS CONDUCTED

The statistical surveys during 1938 were conducted under the immediate supervision of Edward A. Power, Associate Statistician, and the general direction of Fred F. Johnson, Assistant Chief of the Division. These surveys included the collection and dissemination of statistics of the commercial catch and its value, fishing craft and apparatus, and employment in the fisheries. In addition, data were collected on employment and compensation of those engaged in, and products of, fishery wholesale and manufacturing establishments.

Surveys were made during the year covering all coastal sections as well as the Great Lakes for 1937. Statistics of the fisheries of Alaska also were collected by the Division of Alaska Fisheries. of the production of the Mississippi River and tributaries for 1931, which is the most recent year for which a survey of this section was

made by the Bureau, is included in Part 2 of this report.

In addition to the above, statistics were collected on the following special phases: The landings of fish by American fishing vessels at the ports of Boston and Gloucester, Mass., Portland, Maine, and Seattle, Wash. (published monthly); catch of mackerel in the North Atlantic fishery; cold-storage holdings of frozen and cured fish and amount of fish frozen, which are furnished by the Bureau of Agricultural Economics (published monthly); production, consumption, and holdings of marine-animal oils of the United States and Alaska (published quarterly by the Bureau of the Census); production of canned fishery products and byproducts of the United States and Alaska; transactions on the sponge exchange at Tarpon Springs, Fla.; and the volume of the United States foreign trade in fishery products, furnished by the Bureau of Foreign and Domestic Commerce.

The following statistical and marketing agents assisted in the collection and compilation of the statistical data: D. Y. Aska, C. H. Chilton, L. S. Christey, S. C. Denham, F. F. Dimick, M. J. Fraser, R. L. Greer, R. L. Hacker, V. E. Heffelfinger, H. J. Kumin, B. E. Lindgren, C. H. Lyles, C. E. Peterson, C. J. Robbins, V. J. Samson, C. B. Tendick, R. T. Whiteleather, and F. M. Wood.

The reader is especially referred to the section in the latter part of this report entitled "Statistical Survey Procedure," which gives in detail the methods employed in the collection of fishery statistics

and other pertinent information.

### FISHERY MARKET NEWS SERVICE

Following a period of necessary preliminary work devoted to planning, and training of personnel during the latter part of 1937, the Fishery Market News Unit of the Division was intensively engaged during 1938 in the problems connected with the opening of field offices and the issuance of daily reports therefrom. By the fall of 1938 offices were operating at four strategic points in important fish-producing and fish-marketing areas of the country, and a fifth office

was issuing daily reports early in 1939.

The importance of this service to the fishery industry and allied interests is evidenced by the widespread localities and diverse classes of recipients from which requests for this service have been received. Addresses on the mailing lists include every producing and marketing area of importance in the country. Every branch of the fishing industry and numerous groups from allied fields are represented. Among the various classifications on the mailing lists are fishermen and producers; wholesale dealers; brokers; importers and exporters; buyers; retailers; chain stores; cold-storage plants; canners; salters; smokers; byproducts manufacturers; supply firms; transportation companies; Federal, State, and municipal agencies and officials; unions; associations; fishery publications; newspapers; magazines; libraries; banks; and statistical organizations.

In addition to its activities in connection with the direction and administration of the service, the Washington office of the Fishery Market News Service, in January 1939, began the preparation and dissemination of periodic current reviews of fishery market informa-These are prepared in multilith form and distributed to fishermen, dealers in fish, and other interested parties. It is expected that between 10 and 15 of these reviews will be prepared each year. The need for such a service for our fishery interests has long been evident but, obviously, this need has been augmented in recent years as competition in the marketing of fishery commodities has become keener. Fortunately facilities for the preparation and dissemination of such reviews have been developed through the Fishery Market News These periodic reports include summarized data, made available through the daily and monthly reports of the Fishery Market News Service, on movement, prices, and the current status of production and stocks on hand of fishery commodities; articles relating to the fisheries, prepared by members of the Bureau's staff, members of the industry, or other interested parties; excerpts or abstracts from Bureau or other publications relating to the fisheries; and related information.

During 1938 the work of the Fishery Market News Service of the Division was carried on under the immediate supervision of A. W. Anderson, Fishery Marketing Specialist, and the general direction of Fred F. Johnson, Assistant Chief of the Division. Assisting in this work, with headquarters in Washington, D. C., but working both at the headquarters office and in the field, were H. E. Timmis, Fisheries Statistical and Marketing Agent, and P. W. Evans, Junior Fisheries Marketing Agent.

FIELD OFFICES

The locations of the field offices of the Fishery Market News Service have been carefully chosen to be not only of service to the communities near their locations but also to be of the greatest benefit to the industry as a whole. Thus, New York City was selected for the first office, since it is the center of the country's most important consuming area and the market to which fishery commodities are shipped from all parts of the Nation and from foreign countries. The fresh-water and salt-water fish markets of New York exercise considerable influence on

the production and price of fishery products in many areas.

The choice of Boston for the second field office was due to its importance as the center of New England's valuable fisheries, and as a port of landing for large quantities of fresh fish. With a Market News office in Boston, and agents in nearby ports, it has been possible to include in the report data on species, quantity, price, and gear used, covering about 75 percent of the fish landed in New England The catch, usually running well over 600,000,000 pounds annually, is a vital factor in the fresh and frozen fish trade of this country. The value of current detailed data to all who handle this tremendous volume of fish from fishing grounds to markets over the Eastern half of the Nation is obvious.

Chicago was selected for the third field office as the most important inland market for fishery products. Much of the harvest of freshwater fish from the Great Lakes and other interior waters is shipped to this city's wholesale market for distribution. In addition to domestic fish, Chicago receives large quantities of Canadian fresh-water varieties. It also is a marketing area and meeting ground for Eastern haddock and rosefish, Western halibut and salmon, and Gulf Coast shrimp and red snapper, thus demonstrating the distant markets penetrated by our coastal varieties and indicating the possibilities of

our inland States as fish-consuming territories.

The Seattle, Wash., office was the fourth to be established. It is at that port that the greatest quantities of halibut from the valuable Pacific Coast halibut fishery are landed. Landings of salmon for the fresh and frozen trade likewise are important. In addition the receipts and transshipments, chiefly from Alaska but also from British Columbia, of both of these species are considerable. Besides covering the local production and prices, the location of the Seattle office makes it possible to obtain similar daily information from important ports in Alaska and British Columbia. A summary of this information. together with the daily carload shipments out of Seattle and Prince Rupert, B. C., is wired to our Eastern offices, providing their local markets with the advance information of probable Western arrivals, which is so essential a factor in stabilizing market prices.

The fifth Market News office was located in Jacksonville, Fla. In contrast to the other offices Jacksonville is neither an important fishing port nor the center of a large consuming area. It is, however, a very important concentrating, distributing, and shipping center, through which most of Florida's fish passes when destined for Northern markets. From this office it not only is possible to indicate market trends in all Southern varieties of fish and shellfish by reporting the production, price, and shipments of the catch in Florida, but it also is favorably situated for obtaining data on cold-storage holdings in important plants in the South Atlantic and Gulf States, and for compiling current records of the valuable canned shrimp pack which runs over a million cases annually. Of equal importance to the Southern producers is the fact that the Jacksonville office is favorably situated to quickly disseminate wired information on receipts and prices of Southern fishery products and competitive varieties in Northern markets.

The field offices are equipped with mimeographs, folders, and addressing machines to facilitate the expeditious preparation and handling of daily reports. The return address and frank are mimeographed on the report, which is folded and sealed in such a manner that it may be mailed without the use of an envelope. Addresses are stenciled on the reports after sealing. Each office also uses a different color of paper for its reports which not only enables the recipient to quickly identify them in the mail each day but also facilitates their

filing for future reference.

It is estimated that existing fishery market news offices report market conditions affecting over a billion pounds of fish and shellfish

annually.

Reference is made to Figures 1 and 1a which are reproductions of the explanatory statement forwarded to those on the mailing list at the New York Fishery Market News office. Similar statements are furnished from the other offices. Figures 2, 2a, 2b, and 2c are reproductions of a representative daily report issued by the New York office.

The activities of each of the Division's Fishery Market News offices and the coverage of the daily reports emanating from them are here discussed in greater detail.

#### NEW YORK, N. Y.

The New York office of the Fishery Market News Service issued its first Fishery Products Report on February 14, 1938. Reports have been released daily since then with the exception of Sundays and holidavs.

The first section of each daily report includes data on the number of cars and packages of fish and shellfish which have arrived in the metropolitan area by rail freight and express during the preceding 24 hours, or, in the case of intervening Sundays or holidays, the period since the latest report. In the instance of fish, the species rarely can be indicated since it seldom is noted on the bill of lading. For shellfish, however, the species generally is shown. Following the above section of the report, arrivals by coastwise vessels are reported. Imports of fresh and frozen fish and fishery byproducts, such as fish oils, fish meals, etc., are compiled daily from the ship's manifests filed at the local Customhouse, and information concerning the commodity, number of packages, country from which shipped, and the name of the vessel are shown in the daily report.

Direct landings by fishing vessels at the New York market are reported as "hailing fares." Since hailing fares often vary from the actual landings, the exact "weigh-outs" are included in the report for the following day. With the advent of the Fishery Market News Report an accurate record of landings by species at New York City

has been made available for the first time.

Landings by fishing craft at Portland and Rockland, Maine, and at Boston, Gloucester, Provincetown, and New Bedford, Mass., are tabulated and included in the report. The number of craft, type of gear used, and the price of each species landed also are shown. Sections on Pacific coast markets include the transactions on the halibut and salmon exchanges in Seattle, Wash., halibut landings at Prince Rupert, B. C., and the number of cars of fresh or frozen fish shipped East from each of these ports. Such information relating to market conditions at other fishing ports is received in New York by telegraph early each morning.

The amount of fish and shellfish entering or withdrawn from coldstorage plants in the Greater New York area is compiled and shown daily in about 60 classifications. Once each week the current holdings are compared with the holdings of the preceding week and also with the holdings for 4 weeks and 1 year previous. Ten cold-storage firms with 14 plants have cooperated with the Bureau in furnishing these data. Of these plants only two actually freeze fish or shellfish, while the rest are storage plants and receive their goods already

frozen.

As the salt-water market is separate from the fresh-water market, the prices for the two are included in different sections of the report. Managers and salesmen of the various firms are interviewed daily to obtain the day's wholesale price quotations for the various kinds of fish and shellfish. Prices usually are accompanied by essential qualifying descriptions of the commodity, such as size and quality of the product, locality of capture, gear used, and size and type of

package.

At the same time that quotations are being gathered in the salt-water market, a record of the receipts of each firm is obtained. These are compiled and, on the following day, these records furnish the basis for the section of the report showing the total quantity of each species received by States and Canadian Provinces. The record of the receipts of each firm also shows the method of transportation into the market area. In 1939 a summary making use of this information will be compiled for the salt-water market. This summary will classify receipts by origin and by method of transportation, such as truck, express, rail freight, coastwise vessel, and fishing craft.

For the 6 months from March through August 1938, the salt-water market received 79,686,000 pounds of fish; excluding imports and receipts of filleters and some hotel-supply houses. Receipts of shellfish, 22 species in all, are not included in the above figure. The largest poundage arrived by motortruck, accounting for 40 percent of the total. Fishing craft landings were next with 27 percent. Rail freight and rail express followed, with 23 percent and 9 percent, respectively. Coastwise vessels carried only one-half of 1 percent of the

total. Seventy-six different species of fish were received.

FISHERT PHOTOCTS REPORTS

Larkot News reports cover fresh and frozen fishery products only, unless data concerning salted, scoked, canned, or otherwise preserved fishery products are deceed of sufficient interest to be included. All itses are to be understood as fresh when no specification is sade. Prozen products are specifically indicated. Misseographed reports will be issued daily except Sundays and holidays. They are distributed free, by sail, to those requesting these at the above address. Inforestion in the reports also is available to interested parties by telephone or telegraph, collect, as soon as it is compiled.

For the purposes of these reports, New York City, unless otherwise stated, includes the area superwised by the Port of New York Authority. In general, this includes the five boroughs of New York City and an area along the New Jersey shore of the Radson Raver opposite the Manhattan.

The weather report is a record of conditions at the Weather Bureau, 17 Battery Place, in New York City at 7:30 A. M. Eastern Standari Time.

#### RAIL ARREVALS

This section is prepared from reports received from the torminal agents of the various railroad and express companies bringing fishery products into New York City. These reports are received by telephone daily and cover the activities of the carriers for the branky-four hour period ending at 8 M. M. each scoring, or in the case of intervening Sunlays and holidays, the period since the last report. Carloads are listed eccording to the number of carrativing, and less than carload (L.C.L.) lots by the number and, where possible, the type of packages. All shipsants received are classified by the finite or Province from which they were billed. This, however, does not necessarily imply that the fish were produced in the State or Province from which they

#### COASTWISE VESSEL RECEIPTS

This section is prepared by such the same procedure as "Rail Arrivale", the information being obtained from the freight agents of coastwise steamship companies bringing fishery products into New York.

#### LANDIEGS BY FISHING CRAFT

This section shows the "hailing fare" of fishing craft landing at Fulton Market. The "hailing fare" is an estimate of the weight of the catch by the captain before the fare is weighed out. The "landings" used in "Secripts on Salt-water Market" are the "weighed out" or actual fares reported by dealers.

#### MEICH-OUTS BY FISHING CRAFT

This section is compiled from the "weighed out" or actual fares as reported by the dealers purchasing the oatch of fishing craft landing at fulton Market.

#### IMPORTS INTERED

This section includes imports of fishery commodities, except canned and preserved, from foreign countries, and is obtained in the Qustom House at New York City from the ship's manifests. If these sanifests show fishery commodities listed for discharge at nearby Atlantic ports, these items are included with a supplementary statement such as "Due Boston",

#### OTHER PORCES OR MARKETS

This section is prepared from summarised information received each day by telegram from Bureau of Fisheries agents or Mariett News offices in the cities mentioned. Quotations gen-erally are only for varieties of interest to this region.

#### SALT-WATER WARKET

RECIPTS are compiled daily from the records of direct receipts of fresh and frozen fishery products as furnished by the original recoivers in New York City. The "Inndings" by fishing craft shown in this section are "selighed out faress" and not the "bailing fares" shown on the previous day's report. This section does not imitude local cold storage withdramals and imports entered at New York City.

SUPPLY, DEMAND, MARKET AND PRICES are obtained by commulting dealers each morning. Price quotations are actual sales by original receivers in the unana sholesale quantities. Unless otherwise noted, prices are for stocks of good merchantable quality.

#### FRESE WATER MARKET

MOCHIPM are determined from rail freight, express and truck reports and conferences with dealers.

SUPPLY, DECARD, MARKET AND PRICES are obtained in a manner similar to that described under "Salt-Water Market" above.

(Over).

### COLD STORAGE MOVEMENT AND HOLDINGS

Page 2.

This section is compiled from reports obtained daily from cold storage warehouses in New York City. First having cold storage roose in which they store for brief periods for their own use are not included, nor are cold storage warehouses storing fishery products solely for retail sole.

## DERES USED FOR SUPPLY, DEVAND, AND MARKET

SUPPLY	DEMAND	MARKET
Insufficient to quote. Practically no supplies on market. Light. Moderate. Liberal. Heavy. Oversupplied.	No demand. Slow. Light. Loderabe. Good. Active. Deand exceeds supply.	Weak. Dull. Unsettled. Steady. Firs. Active. Strong.

Scattle, Wash.

Twenty-two species accounted for 74,564,000 pounds, or 94 percent of all salt-water fish received. Over 2,000,000 pounds of each of the 11 leading varieties were received, forming 79 percent of the total. In order of their importance they were cod, flounders (blackbacks or winter flounders), mackerel, haddock, butterfish, scup (porgy), yellowtails (dabs), whiting, halibut, shad, and croaker. Receipts of six species ranged from one to two million pounds, or 10 percent of the total. They were gray sea trout (weakfish), fluke (summer flounder), bluefish, gray sole, sea bass, and salmon (Western). The five species received in amounts from one-half to one million pounds were sea herring (including sardines), hake, striped bass, pollock, and tilefish.

Groundfish (cod, haddock, hake, and pollock) accounted for 26 percent of the total receipts during the 6-month period. Flatfishes from the East coast, consisting of blackbacks, flounders, fluke (summer flounder), gray sole and yellowtails, formed 21 percent; and Western halibut and salmon, a little over 5 percent. Varieties caught in large quantities in the Middle Atlantic States, such as butterfish, mackerel, scup (porgy), gray sea trout, sardines, and whiting, made up 10 percent. Of the remaining species, those fish taken in large amounts in other areas as well as in the Middle Atlantic (bluefish, croaker, sea bass, shad, and striped bass) represent 31 percent of the receipts.

The three leading varieties of shellfish received during these 6 months were shrimp, 5,343,000 pounds; lobsters, 2,150,000 pounds;

and squid, 1,671,000 pounds.

Since detailed receipts for the fresh-water market were not collected, exact quantities cannot be given. However, from daily experience in the market it can be stated that whitefish and yellow pike were the leading species among the higher-priced fish, while carp was important

in the lower-priced group.

The distribution of fresh and frozen fish and shellfish in the New York area was effected largely through 92 wholesale dealers, 20 hotel and restaurant supply firms, and 7 brokers. Of the wholesale dealers, 24 handled fresh-water fish exclusively, 3 sold fresh-water and saltwater fish, while the remainder were mainly either salt-water fish or shellfish firms. There were 12 fillet-cutting firms in addition to several of the hotel-supply firms that produced their own fillets.

The delivery of fish and shellfish to local or suburban purchasers generally is made by trucks owned by the buyers. Trucking agencies

and rail express carry the balance.

The retail outlets for fish in New York City have been estimated by the City Bureau of Markets to include 1,500 independent stores that handle fish exclusively, 1,800 meat stores selling fish part of the time, and 700 general markets and chain stores which handle fish.

The wholesale dealers handling fresh and frozen fishery products in New York are centered in a marketing area comprising about four square blocks along the East River near the foot of Fulton Street and just south of the Manhattan end of the Brooklyn Bridge. Known as Fulton Market, the wholesale fish trade has been in this location over a century. Dealers handling salt-water fish and shellfish occupy the greater part of the area, the fresh-water fish dealers practically being limited to one street known as Peck Slip. As there are no direct rail or express connections all shipments must be trucked between the market and the terminals. Many of the latter are situated at a considerable distance across the city. Two freezers adjoin the market

area while the remaining plants storing frozen fish are widely scattered. Fishing vessels discharge their fares at one of several piers extending into the East River. The catch usually is barreled or boxed on the pier for trucking to the dealer's stand or for immediate shipment.

On the site of a market building which collapsed into the East River in 1936, a modern structure has been erected by the city and leased to an organization of the wholesale dealers. It contains well-designed stands on the ground floor with ample office space and dressing rooms above, and is supplemented by a large parking area in front and a receiving platform and bulkhead dock in the rear. Providing many advantages over the older types, the new market building was opened in June 1939. The Fishery Market News Service office is located in a building on the edge of the market area.

The operations of the Fishery Market News Service office in New York City during 1938 were carried on and the daily report issued under the supervision of W. H. Dumont, Senior Fisheries Marketing Agent, assisted by E. C. Hinsdale, Fisheries Marketing Agent (transferred to Chicago during the year), F. J. Anderson, and W. D. Glidden, Jr., Junior Fisheries Marketing Agents, and Joseph Pileggi and Peter DiMarco, Senior and Junior Clerk-Stenographers, respectively.

#### BOSTON, MASS.

The first issue of the Boston Fishery Market News Report was re-It covers the daily activities of this imleased on May 26, 1938. portant fishing port in considerable detail. Hailing fares of the offshore and inshore fleets landing at Boston Fish Pier-otter trawlers, draggers, line trawlers, hand liners, gill netters, purse seiners, and harpooners—are listed in one large table, which also includes the first sales prices of each species in the catch. To aid in the orderly marketing of Boston's huge supply of fish much additional information is The current landings at other ports, both nearby and distant-Gloucester, New Bedford, and Provincetown, Mass.; Portland and Rockland, Maine; New York, N. Y.; Seattle, Wash.; and Prince Rupert, B. C.—are received by telegraph and made available early each morning. Rail freight, rail express, and coastwise steamship arrivals are not only covered for the period since the preceding report, but a section for additional receipts includes shipments by rail and steamship, mostly fish and shellfish from Canada, due to arrive later in the day. Other daily compilations include imports of fishery products from all countries, prices paid to shippers of fishery products by dealers on the pier, and the movement of over 30 fishery commodities into and out of cold storage. Weekly, comparative holdings are published for the current and preceding weeks and for 4 weeks and 1 year previous. In order to be of the greatest aid to the industry, the daily report is completed and delivered to the dealers on and in the vicinity of the pier each forenoon and, for delivery outside Boston, is placed in the mail at noon.

Boston is primarily a production center, supplying enormous quantities of fresh and frozen fishery products to the Nation. It is well situated with the natural advantages of an excellent harbor and nearness to both producing and marketing areas. It also has good

handling and shipping facilities.

The Boston Fish Pier, the largest in the world devoted exclusively to the fish business, is the outgrowth of the importance of the fishing industry to Boston. The pier itself extends 1,200 feet into the harbor and is 300 feet in width, the entire property comprising 537,000 square feet. It was built at a cost of \$3,000,000 and was opened on March 30, 1914. Approximately 350,000,000 pounds of fish are landed at the pier annually.

The pier is divided by a wide center street flanked on each side by buildings especially designed and constructed to house the activities of the wholesale dealers occupying the individual stores. Besides sufficient space for the receiving, processing, packing, and shipping of fish, they also contain offices and storage rooms. Each store has a front entrance on the center street and a rear entrance on a mooring side of the pier, thus making it possible for fish to be taken directly from the vessel into the rear entrance, processed, packed, and delivered to a waiting truck at the front entrance.

A large cold-storage plant is located at the shore end of the pier. It has a capacity of 15,000,000 pounds of frozen fish as well as adequate freezing and icing facilities. In addition, there are three other public cold-storage plants near at hand that freeze and store fish.

The New England Fish Exchange is located in a building on the outermost end of the pier. It is here that all trips of fish are sold. The Exchange is open early each morning, except on Sundays or holidays. If desiring to sell in or over the Exchange the captain of each vessel is required to register his catch with an officer of the Exchange before it can be auctioned. The detailed fare of each individual trip is posted on blackboards for the inspection of the buyers. All bidders or buyers must be members of the Exchange. Every effort is made by the vessel captains to make port prior to the open-

ing of the Exchange in order to obtain top prices.

The bidding commences at 7:15 a.m. Each captain has the alternative of making his own sale or engaging an authorized agent to do his selling for him. The auctioneers are on a raised stand in the center of the Exchange around which the buyers gather. The auctioneer announces the amount and kind of fish he has to offer, accepts bids, and sells to the highest bidder. The buyer may buy part or all of any trip. All purchasers are presented with settlement slips which must be paid before the closing of that day's business. The sales continue throughout the day until all fish are sold. Each morning the sales begin with new arrivals, since fish seldom are carried over unless the owner or captain finds it advantageous to do so.

The Boston Fish Pier is a scene of great activity throughout the

Fish is being moved in all directions as soon as the first sales are consummated. From the vessel's side to the dealer's premises the fish generally are transported in large two-wheeled carts, hauled

by hand or motortrucks.

Good transportation facilities add to the importance of Boston as a producing center. On the pier a railroad spur on each side of the cold-storage plant makes it possible to load directly into cars or unload directly into the freezer. Two large trucking firms have platforms to receive and send shipments. All of the stores have loading platforms to accommodate trucks of various sizes. The finished products are loaded at these points for local or State-wide distribution. In addition, large refrigerated trucks receive cargoes for distant delivery. These trucking lines maintain daily schedules and extend as far west as Denver. A fleet of trucks carries express shipments from the pier to rail terminals. Much of the fish shipped to New York is transported in carlots on special freight trains operating on a fast schedule.

There are about 90 wholesale fish establishments and manufacturers of fishery products in Boston. They handle fresh and frozen fish and shellfish, and produce fillets, salted, smoked and canned fish, crab and lobster meat, cod-liver oil, glue, fish meal, and fish oil. In addition, there are a number of commission merchants who handle

shipments of fish and shellfish to the Boston market.

Boston is not only an important producing center, but it also offers a market for fish from other sections of the country. Receipts of salmon and halibut from the Pacific Coast; frozen swordfish from Japan; frozen shrimp from the Gulf; fresh-water fish from the Great Lakes and inland States; and large quantities of lobsters, other shell-fish, and fish from the Maritime Provinces of Canada and from New-

foundland add to the supply of native varieties.

The importance of Boston as a fishing port is emphasized by the amount of fish landed during the last 7 months in 1938, the period during which the Market News office operated. Landings totaled 174,569,000 pounds, valued at \$4,249,000, during this period. Haddock accounted for 67,565,000 pounds, valued at \$1,596,000, or 39 percent of the total receipts and 38 percent of the total value. Cod followed with 40,173,000 pounds, valued at \$873,000. This represents 23 percent of the landings and 21 percent of the value. Rosefish (redfish) came next in poundage with 18,132,000 pounds, valued at \$222,000, forming 10 percent of the catch and 5 percent of the value. Mackerel, with 11,545,000 pounds, valued at \$386,000, made up 7 percent of the receipts and 9 percent of the value. Species landed in lesser quantities included, in the order of their importance, pollock, flounders (blackbacks, dabs, gray sole, lemon sole, and yellowtails), whiting, hake, cusk, swordfish, halibut, and wolffish (catfish).

The above totals do not include the fish landed and sold to dealers across the harbor on Atlantic Avenue; the quantity landed by undertonnage boats; imports; nor the receipts of fish and shellfish by truck,

rail express, rail freight, and coastwise vessels.

Early in 1939 the Boston office began to release a monthly summary of the receipts and prices of a number of the more important species landed at the Fish Pier and sold through the New England Fish Exchange. The summary is a daily compilation of the quantities landed, the first sales prices, and the average prices. A series of comparative figures for the current month, the preceding month, and the preceding year also are included.

The activities of the Boston office and the issuance of the daily report and the monthly summary were under the supervision of B. E. Lindgren, Senior Fisheries Marketing Agent. He was assisted by C. W. Morrison, Junior Fisheries Marketing Agent, and J. J. O'Brien,

Senior Clerk-stenographer.

#### CHICAGO, ILL.

The Chicago Fishery Market News office, through a daily Fishery Products Report and a monthly summary of wholesale receipts, records the receipts, prices, and similar valuable information con-

cerning fishery products, mainly fresh water, entering Chicago. The first daily report was released September 1, 1938. The daily report provides current information on the arrivals of fish by means of a tabulation of truck, rail express, and rail freight arrivals each morning. Species and poundage are shown as well as the shipping State or Canadian Province. Market prices received by shippers are quoted daily in considerable detail. The movement of fishery products into and out of cold storage is reported daily for approximately 45 varieties. Each week holdings are published for the current and preceding weeks and for 4 weeks previous. When sufficient data have accumulated, holdings for the previous year also will be incorporated.

Summaries of the wholesalers' receipts have been issued monthly since September 1938. They include tabulations of receipts by quantity, species, method of transportation, and State or Province of

origin.

During the first 6 months the Chicago office operated, nearly one-fourth of Chicago's fresh- and frozen-fish receipts consisted of two species—lake trout and halibut. The large contribution of these two single species to the total receipts is surprising, in view of the fact that scores of other varieties of fresh- and salt-water fish are handled in the local market.

The species leading in importance with respect to receipts included, in addition to lake trout and halibut, the following, in order: Sauger, shrimp, yellow perch, oysters, whitefish, lake herring, yellow pike, rosefish, carp, and chubs. These 12 species accounted for more than 80 percent of the total receipts for the 6 months. During the same period, 18 additional species of fresh and frozen fresh-water fish, 32 additional salt-water species, and 13 other shellfish and miscellaneous commodities—a total of 75 species—were received in Chicago.

During the 6-month period aggregate receipts of fresh and frozen fish and shellfish in the Chicago market amounted to 19,200,000 pounds, or an average of 3,200,000 pounds each month. This quantity would supply 1 pound of fish per capita each month to Chicago's population. However, a considerable part of the fish received in Chicago is not consumed locally but is reshipped to communities outside Chicago. During the month of February 1939 reconsignments of fishery commodities amounted to about 1,000,000 pounds, or nearly one-third of the total receipts during the month. Such reconsignments are said to reach as high as 60 to 75 percent of the total receipts in some months, but in others they may amount to only 20 to 25 percent, or less.

As might be expected, due to its closer proximity to the fresh-water producing areas of the United States and Canada, Chicago is primarily a fresh-water fish market. About 3 pounds of fresh-water varieties are received to each 2 pounds of salt-water species. It is interesting to note, however, that 4 salt-water species are included among the 12 most important varieties. These are halibut, from the Pacific Northwest; shrimp, from the Gulf Coast; oysters, from the Atlantic Coast; and rosefish, from New England. The fresh-water varieties emanate largely from the Great Lakes of the United States and Canada; Lakes Manitoba, Winnipeg, Rainy, Dauphin, Nipissing, and Nipigon, Lake of the Woods, and the Pigeon River of Canada; and the Mississippi River and tributaries of the United States.

Virtually all fish received in Chicago arrive by three types of car-ers. These are, in order of their importance: Rail freight, motortruck, and rail express. While rail freight leads among the types of carriers when considering all receipts, we find that it follows the motortruck when considering receipts from domestic sources only. predominance of the motortruck in carrying domestic fish is influenced especially by the hauling of fresh-water fish from neighboring States. However, the truck also is an important factor in more distant hauls; for instance, truck receipts of rosefish from Massachusetts for the 6month period amounted to the equivalent of nearly 30 carloads. siderable quantities of other groundfish also were received by truck from New England and truck shipments of shucked oysters from Chesapeake Bay were important. In earlier years steamers transported quantities of fresh-water fish from lake ports to Chicago by water. More recently, this factor in the receipt of fish at this market is considered negligible. Between a million and a million and a half pounds of fish normally are landed each year on Chicago's lake front by local commercial fishermen.

Chicago's distribution of fresh and frozen sea food is largely effected through its 62 wholesale dealers, 10 brokers, 10 hotel and restaurant supply firms, and 14 fish smokers; all of which are primarily direct receivers. Some 200 retail dealers who handle fish exclusively may at times receive direct shipments; however, most of their requirements

are purchased through the Chicago wholesale market.

With only a few exceptions Chicago's wholesale dealers, who are direct receivers of fishery products, are concentrated in a central location west of the downtown business section. All receipts must be brought to this market by truck since it is not located on the water nor is it served directly by rail. Cold-storage plants are situated in the same general area, being readily accessible for either the storage or withdrawal of fishery products. The Fishery Market News Service office is within one block of the market area.

Delivery of fish from the Chicago wholesale market to local and suburban buyers may be effected either by trucks owned by the wholesale dealers or in the trucks of the buyers. The services of trucking agencies or rail express are used for longer hauls. Frequently, in the instance of carlot sales, the entire car is diverted to the buyer without a preliminary opening in Chicago. This occurs quite frequently in

sales of halibut and salmon arriving from the Pacific Coast.

The old-style fish hucksters are factors of decreasing importance in the distribution of Chicago's fish, but they are being replaced by modern so-called hucksters who operate up-to-date refrigerated trucks on established routes throughout the outlying sections of the mid-Central States.

During 1938 the activities of the Chicago office and the issuing of the daily report and monthly summary were supervised by E. C. Hinsdale, Fisheries Marketing Agent, assisted by B. F. Lucarz, Junior Clerk-stenographer.

#### SEATTLE, WASH.

The Seattle office of the Fishery Market News Service issued its first daily Fishery Products Report on October 1, 1938. The report includes data on the daily receipts and prices of fishery products at Seattle, with separate sections for each major fishery. Statistics on

imports of fresh, frozen, and cured fishery products from British Columbia and coastwise vessel receipts from Alaska are also shown. Other features include halibut landings and prices at Prince Rupert, as well as carloads of fish shipped daily from Prince Rupert and Seattle.
Through daily telegrams from New York and Boston, data are included on Eastern market supplies and prices of West coast fish and competing species, as well as the cold-storage movement and holdings of important varieties.

An addition to the Seattle Market News report, effective May 1, 1939, is the daily coverage of halibut and salmon landings in southeastern Alaska. The receipts and prices of these species at Juneau, Ketchikan, Petersburg, and Sitka on a daily basis, and Wrangell on a weekly basis, are now incorporated in these reports. During 1938, Alaska halibut landings amounted to nearly 8,000,000 pounds, and troll-caught salmon landings in southeastern Alaska exceeded 10,000,000 pounds. Information on the daily receipts and prices of these species

in Alaska adds materially to the value of the reports.

During the 12-month period ending December 31, 1938, there were nearly 51,000,000 pounds of fishery products landed at Seattle by vessels of the halibut fleet and other local craft. These products had a basic value of \$3,275,000 to the fishermen. In addition, it is estimated that approximately 20,000,000 pounds of halibut and salmon were received in Seattle by coastwise vessels from Alaska and freighters

from British Columbia.

Of the Seattle fish receipts, two species—halibut and salmon—contributed over 72 percent; halibut leading all species with 41 percent of the total receipts. Only 8 other species of fish were received regof the total receipts. Only 8 other species of fish were received regularly by Seattle wholesale dealers during 1938. These, in the order of their importance, were: Flounders, 4,048,500 pounds; sablefish, 2,756,400 pounds; "lingcod," 2,708,200 pounds; herring, 727,400 pounds; rockfishes, 620,500 pounds; cod (true cod), 432,200 pounds; smelts (eulachon and silver), 320,800 pounds; and perch, 121,900 pounds. There were also approximately 800,000 pounds of albacore tuna received in Seattle, nearly all of which was frozen for canning at Anacortes. In addition, small quantities of California mackerel, herricular honito, sea hass, and vellowfin and bluefin tune are also barracuda, bonito, sea bass, and yellowfin and bluefin tuna are also

received for the Oriental trade. Of the shellfish receipts at Seattle, the "Dungeness" crab is the leading item, amounting to 1,752,900 pounds, valued at \$79,068 to the Most of these crabs are taken in the ocean off Willapa fishermen. Other species of shellfish received in Seattle and Grays Harbors. Other species of shellfish received in Seattle include Pacific and Olympia oysters, hard-shell clams (butter and little-neck), razor clams, bay scallops, shrimp, octopus, and squid. The Olympia oyster is one of the highest-priced species of shellfish in this country, selling wholesale in Seattle at \$8 per gallon. Octopus and squid are consumed almost entirely by the Orientals. In this connection it is interesting to note that the Puget Sound production of squid is not nearly enough to take care of the local demand. Considerable quantities of fresh squid are received from Monterey, Calif., and last fall a carload of frozen squid was shipped from Massachusetts to Seattle. The local supply of shrimp is nearly exhausted, and Seattle depends largely on Alaska shrimp meat for this sea food. There are

occasional shipments of California shrimp to Seattle, and an attempt is now under way to market frozen headless shrimp from Texas in Seattle.

Over 90 percent of the Seattle wholesale fish business is conducted by 12 establishments. Of these, six firms handle over 75 percent of the fishery products coming into Seattle. There are two fish exchanges, one for halibut-fleet landings and the other for selling troll-caught salmon of the Fishermen's Cooperative Association. The halibut exchange is operated by 10 wholesale firms and is called the Seattle Fish Exchange. Bidding is open only to member dealers, and the minimum bid change permitted is one-eighth cent per pound. The hailing fare of a halibut vessel must be posted on the board by 9 a. m., if it is to sell that day. A dealer must bid on the entire fare. There are no split trips sold over the exchange.

The salmon exchange, operated by the Fishermen's Cooperative Association, is similar to the halibut exchange. Bidding is graduated in eighths of a cent, and is open only to members of the Seattle Fish Exchange. Truck deliveries of salmon from the Washington coast, as well as deliveries by fishing craft and transporters from Neah Bay, are sold over this exchange. Receipts of other fishery products at Seattle are by direct purchases. In this case a price is usually set at the beginning of the season and is generally constant throughout its duration. Most of these prices are for delivery in Seattle, which leaves the trucking charges to the fishermen. As a rule the dealers send their fishermen a check once a week when several deliveries are made during the week.

There are five fish freezers and cold-storage plants in Seattle, in addition to one cold-storage plant for mild-cured salmon and salted herring. Two of the fish freezers are owned by wholesale fishery firms, two are privately owned freezers, and the other two are

operated by the Port of Seattle.

Fishery products arrive at Seattle almost entirely by vessel or truck. An occasional "less than carload" rail shipment from Vancouver, B. C., or Astoria, Oreg., is received. In the past there have been carloads of fish and shellfish to Seattle from the Atlantic Seaboard, but these are now rare. At times Seattle receives large quantities of fresh and frozen halibut and salmon from Alaska and British Columbia. Arrivals of over 250,000 pounds of fish from Alaska in 1 day are not unusual. Receipts of white king salmon for kippering and large red kings for mild cure from British Columbia have exceeded 3,000,000 pounds annually at Seattle.

Unlike most cities, Seattle's wholesale fishery dealers are not concentrated in one location. There is no "fish pier" or wholesale fishtrade section. Most of the dealers are located on piers at which fishing craft may discharge their fares. Although the dealers are situated at widespread intervals along the water front the arrangement is not necessarily inefficient, since most vessels sell their entire catch to one firm. All companies on the water front are adequately served with spur tracks and facilities for transportation by truck over short or long hauls. The Fishery Market News Service office is located near the fish exchanges and the greatest concentration of dealers.

The cold-storage plants are spread out as widely as the dealers. Most

are served both by steamship and railroad.

During 1938 the Seattle office was operated and the daily reports were issued under the supervision of V. J. Samson, Fisheries Statistical and Marketing Agent, assisted by K. G. Nordquist, Junior Clerkstenographer.

#### JACKSONVILLE, FLA.

Late in 1938 the Jacksonville Fishery Market News office was established and preparations made to issue a daily report on fishery products. The first report was issued on March 6, 1939. Current data are published covering the production and prices of fish and shrimp produced on both coasts of Florida—from Fernandina to the Florida Keys on the Atlantic Coast, and from Everglades to Pensacola on the Gulf. Since the coast lines are long, and the fishing areas not only numerous but also widely separated, it is not possible to procure complete information on all varieties and for all localities with the funds and personnel available. To improve this situation part-time agents are being placed in several of the more important production centers on both coasts in order that a full report may be secured for these areas. It is believed that complete knowledge of the activities in several areas on each coast will be more valuable than partial information from the whole State, and will indicate the

trend of production and price in the State generally.

Since Jacksonville is an important distribution point for fishery products bound for markets in other States, a record of outgoing shipments by rail freight, rail express, and motortruck is carried in the report. Through a cooperative arrangement with the Florida State Department of Agriculture, data on truck shipments are obtained in considerable detail. This information includes the quantity of each species and the destination by State. Data on the county of loading in Florida also are secured but not published. Receipts and prices of Southern fish and shellfish and competitive Northern species on the New York market are received by wire, and reported together with a summary of landings and first sales prices at Boston. The movement and holdings of fishery products in a number of the most important cold-storage plants in the South Atlantic and Gulf States are shown on a weekly basis with comparative holdings for the preceding week and for 4 weeks previous. The cold-storage plants are located from North Carolina to Texas. The varieties stored are divided into 34 classifications, 24 being salt-water fish, 4 fresh-water fish, and 6 shellfish.

At frequent intervals, through the cooperation of the Food and Drug Administration, data on shrimp packed in canneries utilizing its Seafood Inspection Service are released. The information includes, for each period and for the season, the number of plants operating, the number of days operated, the quantity of raw shrimp received, the pounds of raw shrimp packed, and the number of standard cases of shrimp canned. The shrimp canneries number about 40 and are situated in Georgia, Florida, Alabama, Mississippi,

Louisiana, and Texas.

The Fishery Market News Service office is located in the downtown section of Jacksonville, one block from the St. Johns River. In this area most of the wholesale fish dealers are concentrated. They

are favorably situated with respect to all forms of transportation utilized for either incoming receipts or outgoing shipments. Spur tracks are available near most of the establishments for carlot shipments, and the express terminal is easily reached with a minimum of interference from city traffic. Fishing craft and commercial steamships berth at piers extending into the river. Shipment by truck is facilitated, since the location is but one block from the main highway traversing the city. Although the cold-storage plants do not adjoin the wholesale fish-trade section they are readily accessible.

In 1938 the Jacksonville Fishery Market News office was supervised by S. C. Denham, Fisheries Statistical and Marketing Agent.

He was assisted by J. E. Borum, Junior Clerk-stenographer.

### COOPERATIVE MARKETING

The cooperative marketing unit of the Division was under the direction of L. C. Salter from the time of its organization in 1935 until December 31, 1937, when he resigned from the Bureau's service to accept a position with the Tennessee Valley Authority. Following this the unit was administered directly under the chief of the Division until August 1938 when Ralph Russell, Associate Fishery Economist, was appointed to take charge of the unit.

Since his resignation, Mr. Salter has been working on the preparation of a report incorporating the results of much of his survey work with the Bureau. This report, when completed and released, will cover much valuable information concerning the operation of fishery

cooperatives.

During 1938 work was continued on the collection of data relating to fishermen's cooperatives and other organizations in this country and abroad. During the past year cooperatives have been organized in several States. Appeals for assistance in the organization of cooperatives have been received from many sections of the country, and such assistance has been rendered as has been possible with the limited staff and funds available for this work.

Arrangements have been completed to enlist the aid of statistical and marketing agents of the Bureau, who visit virtually all the commercial fishing areas of the United States each year, to assist in keeping the data on fishermen's organizations current. They will obtain reports from fishermen's cooperatives during the course of their surveys and forward them to the Washington office for study. This procedure should facilitate the maintenance of adequate files on the

status and activities of domestic cooperatives.

A possibility for further cooperative activity by fishermen, which seems at present to have been but little explored, is the opportunity of joining cooperatives already formed. For instance, supplies of various kinds, particularly petroleum products, are handled by cooperatives operating over large areas. Fishermen in some cases may become members of these cooperatives or induce the cooperatives to set up branches in locations accessible to the fishermen. Credit unions, which are cooperative savings and loan associations, have been extensively developed. These would seem to offer to fishermen a possibility of assistance through accumulating and borrowing capital by membership in such organizations. Cooperatives furnishing groceries and

other consumers' goods also are available to fishermen in some parts of the country. Through joining these and other cooperatives, fishermen may make economic gains and learn cooperative techniques which may apply in their own occupation.

The Bureau offers its assistance to groups of fishermen interested in the forming of cooperatives to the extent that its facilities can be

devoted to this end.

#### TECHNOLOGICAL INVESTIGATIONS

As has always been emphasized in previous annual reports of this Division, the primary purpose of our technological investigations is to bring about more efficient and more profitable utilization of the products of our fisheries. This is in line with, and in the best interests of, the conservation of the natural resources of this country because, in its broader sense, conservation includes the wisest and most complete utilization of our fishery harvest that modern science can make Thus, technological investigations of the Bureau of Fisheries have been devoted to the improvement of existing methods and the development of new methods of utilization and preservation of aquatic products. Widening the uses of these products is another important phase of the work of our technologists. As the result of such studies during the past years, our technologists have been able to suggest gradual improvements in the industry and some of these suggestions have been placed in practical use. It is believed that there could be more widespread utilization of these improvements to the ultimate profit of the industry.

Furthermore, our technological investigations, from time to time, have resulted in outstanding discoveries which have been the basis of new industries in the fisheries. A number of these discoveries were discussed in the 1937 annual report of this Division and referred to such subjects as the new domestic industry of producing fish oils and fish-liver oils as sources of vitamins A and D for both human and animal nutrition, the rapid discoveries and developments in the quick-freezing industry in which technologists of this Bureau pioneered, and the improvements and increases in the manufacture of fish meal

as a highly important ingredient of livestock feeds.

#### LABORATORIES

During 1938 the Division carried on its technological studies under the direction of Dr. J. R. Manning, Senior Technologist, at its laboratories located in Washington, D. C., College Park, Md., and Seattle, Wash. In addition, members of our technological staff cooperated in the conduct of investigations in the laboratories of the University of Maryland and Maryland State Agricultural Experiment Station at College Park, Md.; the University of Washington, Seattle, Wash.; and Washington State College, Pullman, Wash.

By means of funds allotted from the Public Works Administration and the Works Progress Administration, improvements were made during the year to the technological byproducts laboratory building and the chemical laboratories in Seattle, Wash. These included the placing of a brick veneer on the outer walls of the byproducts building, painting the interior, and staining the roof of this building, installing compressed-air lines and an additional sink, including lead linings in

the floor drains and sumps, painting the walls in the chemical laboratories, and constructing a tunnel dryer and a combination brine and

sharp freezing cabinet.

The major portion of the work of the Seattle laboratory organization in 1938, as in past years, consisted of investigations of byproducts. although some studies were made in the general field of preservation of fishery products for food. The greater part of the work of the College Park laboratory organization was devoted to chemical and bacteriological studies in connection with the preservation of fishery products for food, and pharmacological and nutrition studies of the constituents of fishery products, although some work was done on byproducts in connection with the chemical preservation of fish waste The work of the Washington laboratory was confined to studies on the canning of fishery products.

The following personnel, in the various laboratories listed below, contributed to the technological investigations described in the

ensuing pages of this report:

College Park, Md.—J. M. Lemon, Technologist in Charge; W. T. Conn and S. R. Pottinger, Assistant Technologists; Dr. H. W. Nilson, Assistant Pharmacologist; C. F. Lee, W. B. Lanham, Jr., and A. L. Fowler, Junior Chemists; J. F. Puncochar and Dr. R. J. Reedy, Junior Bacteriologists; H. E. Crowther, C. E. Swift, and R. H. Flowers, Research Associates; L. F. Ortenzio, H. F. Kraybill, N. G. Sprague, L. J. Barton, R. C. Dawson, Roscoe Dwiggins, J. D. Rollow, D. K. Worgan, and Ned Oakley, student assistants.

Seattle, Wash.—R. W. Harrison, Technologist in Charge; M. E. Stansby, Assistant Technologist; Charles Butler, William Clegg, Jacob Ash, and Mrs. Marie Sater, Research Assistants.

Washington, D. C.-N. D. Jarvis, Associate Technologist.

#### PRESERVATION OF FISHERY PRODUCTS FOR FOOD

During 1938 studies on the preservation of fishery products for food consisted of the following projects: Studies of rancidity in fish; studies of lactic acid as a possible index of decomposition in frozen fish: identification of canned salmon; changes in the composition of pink salmon (Oncorhynchus gorbuscha); composition of commercial species of fish taken on the Pacific coast; and canning aquatic products.

#### STUDIES OF RANCIDITY IN FISH

This project has been under investigation for the past several years. It is one which presents some very difficult technical problems. We have been conducting it in cooperation with the Musher Foundation, Inc., of New York City, as that organization is interested in the application of certain antioxidants in all of the food industries and had already carried out considerable original research on the problem of preventing the various forms of rancidity in different types of foods before our technologists undertook a study of the aspects dealing specifically with fishery products. The Bureau's Seattle and College Park laboratories have both been working on the project, but dealing with different phases of it, and the Musher Foundation has employed and stationed research associates in both of these laboratories for this Progress reports have been published from time to time,

as described in previous annual reports of this Division and, during 1938, a report was given at the September meeting of the American Chemical Society in Milwaukee, Wis. This report deals specifically with the use of a water extract of the active principle of oat flour as the antioxidant. Boston mackerel were treated with this extract and then frozen by the usual commercial method. As a means of comparison, control samples of Boston mackerel were given the usual commercial handling without the application of the extract of antioxidant and were frozen. Periodic examinations of these samples over a period of 6 months indicated that those fish treated with the oat flour extract were of definitely superior quality to the untreated samples.

These results are very interesting because earlier studies of the direct application of oat flour, or solvent extracts prepared from oat flour, gave only a very mild protective action, not sufficiently pronounced to attract the interest of the fishery industries for commercial application. Moreover, the direct application of oat flour detracted from the appearance of the resultant product and the solvent extracts were of limited application because of their oily nature. However, tests conducted in the College Park and Scattle laboratories thus far of the water-soluble extracts of oat flour and concentrates prepared therefrom did not affect the appearance of the fish so treated and, as indicated above, were much more effective in retarding ran-Therefore, these water-soluble extracts of oat flour are being tested on fresh salmon prior to canning, mild-cure salmon, kippered salmon, frozen salmon, and frozen halibut. In the case of the mildcure and kippered salmon, the extracts were used in conjunction with the normal brining processes while in the frozen products the extracts are being used in connection with washes prior to freezing and in the Since these latter tests are now being run under comglazing bath. mercial storage conditions, sufficient time has not elapsed to permit definite conclusions. So far, only moderate improvement has resulted. Such results must be attributed more to the extreme difficulty of retarding rancidity in fish oils than to the lack of effectiveness of the cereal flour products as antioxidants.

# STUDIES OF LACTIC ACID AS A POSSIBLE INDEX OF DECOMPOSITION IN FROZEN FISH

Progress on this project was interrupted during 1938 because of the resignation of the investigator assigned to the problem. Another

chemist has recently been assigned to the work.

It is known that lactic acid rises to a maximum content in fish muscle during the rigor of death, and the importance of muscular rigor, in its relation to the onset of spoilage in sea fish, has been emphasized by other investigators in this field. It has also been shown that the alkaline reaction of fish muscle and the accompanying onset of spoilage of the fish follows after the loss of muscular rigor. Thus it is evident that, since spoilage occurs after the lactic acid content of the fish muscle reaches a maximum, the determination of lactic acid in fish flesh before and during a period of cold storage is of value in obtaining direct knowledge of the processes of decomposition of fish.

Recently, sea trout have been obtained by our technologists from Chesapeake Bay and have been frozen under varying conditions of freshness. Lactic acid determinations have been made on these fish before storage and at regular intervals during storage. Results obtained at this point of the investigation indicate that the lactic acid content of sea trout muscle varies from 0.05 percent to 0.40 percent. Sea trout frozen while in muscular rigor show a higher lactic acid content than those frozen under the other conditions of relative freshness or decomposition.

#### IDENTIFICATION OF CANNED SALMON

Studies on the possibility of differentiating between the species of salmon, on the basis of the refractive index and color of the free oil in the canned product, were continued. A statistical analysis of the data obtained during the preceding year indicated that the data at hand were not sufficient for satisfactory interpretation. Accordingly, additional samples have been taken, and sampling will be continued until enough data have been obtained to permit a thorough investigation of the reliability of such a method for identifying the various species of salmon after canning.

# CHANGES IN THE COMPOSITION OF PINK SALMON (Oncorhynchus qorbuscha)

Pacific salmon, especially the pink or humpback, are known to undergo considerable physical change during their spawning migration. This change is manifest by a gradual decrease in the pigmentation of the flesh, softening of flesh texture, and a decrease in the fat content of the edible portions. Generally speaking, the fish are believed to become poorer in quality until a point is reached where they are considered no longer suitable for canning. Salmon, however, are consumed as a protein food and very little information is available regarding the relation of these apparent changes to the nature of the protein present.

A chemical study of this problem was undertaken during the summer of 1937 and was continued during the past year. The actual chemical determinations have been completed and the data are being assembled and analyzed for publication. While it is considered inadvisable to draw definite conclusions at this time, the data, which involve analyses for moisture, fat, protein, ash, soluble nitrogen, heat coagulable soluble nitrogen, free amino nitrogen, copper precipitable nitrogen, phosphotungstic acid precipitable nitrogen, and the amino acids cystine, tyrosine, tryptophane, and arginine, would indicate that the pronounced change in the appearance and texture of the flesh is accompanied by much less change in its chemical nature.

# COMPOSITION OF COMMERCIAL SPECIES OF FISH TAKEN ON THE PACIFIC COAST

The Bureau of Fisheries receives numerous inquiries from both the producer and consumer of fishery products regarding the composition of various food fish and the relative amounts of wastage involved in dressing. In seeking the necessary information, it is found that much of the data required is either not available or of a very fragmentary nature. Accordingly, during the past year studies were undertaken

for the purpose of determining the relative proportion of edible and inedible material in food fish taken commercially on the Pacific coast and to determine the "proximate" chemical composition of the edible portion. The measurements include percent dressed weight, percent trimmings, percent viscera, percent liver, percent flesh, percent bone, percent skin based on the round weight of the fish, the proportion of the dressed weight which is flesh, bone, and skin, and percent moisture, fat, protein, and ash in the edible portion. Numerous samples of each of 22 different species of fish have been analyzed to date. These are: Albacore tuna, sea bass, gray cod, "lingcod," red cod, rock cod, lamprey eel, starry flounder, halibut, herring, sea perch, pilchard, orange rockfish, sablefish, chum salmon, pink salmon, silver salmon, sockeye salmon, roe shad, English "sole," king "sole," and turbot. The analyses are being continued and the data will be assembled in report form.

#### CANNING AQUATIC PRODUCTS

For the past several years one of our technologists has been engaged in the development of methods for home or noncommercial canning of fish. Several publications, described in previous annual reports of this Division, have been published by the Bureau on this subject. The work on this project has now been completed and a final report has been prepared for publication. This report will include recommended methods of canning many fishery products not discussed in previous publications on the subject. These methods are designed primarily for the housewife or for the canning of fish in small quantities in the home, and cover enough species of fish so that all sections of this country where fish are taken may benefit from the results of this work. The species of fish and shellfish for which home canning methods have been developed, are: Alewives, herring, alewife or river herring roe, carp, suckers, fish roe, mackerel, lake trout, whitefish, mullet, mackerel (ready cooked salt-mackerel style), smoked mackerel and mullet, salmon, shad, spiced fish, king mackerel, mackerel and swordfish (tuna style), whiting, whole clams, minced clams, oysters, Atlantic and Gulf coast crab, Dungeness or Pacific coast crab, devilled crab. crab gumbo, crab soup (Norfolk style), shrimp (wet-pack method), fish chowder, New England clam chowder, and Manhattan or Coney Island clam chowder.

Studies on the canning of the blue crab were continued, with the preparation of experimental packs under commercial conditions and on a semicommercial scale. Other experimental packs were made to confirm conclusions reached in the work of the previous year. Examination of these packs of crab meat showed no deterioration or discoloration after a storage of as much as 18 months. We expect to

publish the results of this work during the coming year.

As has been discussed in the annual reports of this Division in recent years, there has been a considerable demand from the various commercial fish-canning industries of the United States for a comprehensive manual describing existing methods of canning fish and shell-fish in the United States, thus bringing this information up-to-date with any recommendations for improvements that a technical survey might reveal. Surveys of the fish-canning industries of the South Atlantic and Gulf of Mexico areas, and of the Pacific coast, were made

during 1938; thus completing the study for the whole country. A full report covering the information obtained in this Nation-wide survey, showing cannery plans, illustrations, and other useful information, is almost finished and will be ready for publication in the near future.

In addition to the above-mentioned investigations in the canning of fishery products for the home and in commercial operations, interest in the Bureau's work in this field has been stimulated to the point that we have had to supply a rather complete technological consulting service to the industry on the various technical problems in fish canning.

### BACTERIOLOGICAL STUDIES

During 1938 the need for expanding our facilities for bacteriological research became acute and, as indicated earlier in this report, the Bureau established at College Park, Md., a new bacteriological laboratory in additional space provided free of charge by the University of Maryland in its Horticultural Building on the same floor and across the hall from space now occupied by the Bureau's other technological laboratories. The separation of the bacteriological laboratory unit from the chemical laboratory has been of considerable help in furthering the work of this unit.

## STUDIES OF ULTRAVIOLET RAYS IN KILLING BACTERIA

This project was begun late in 1937 and a part of it has been completed. Results on the completed portion are described in Investigational Report No. 43, "Some Effects of Ultraviolet Irradiation of Haddock Fillets," published by the Bureau. According to the conclusions in this paper, irradiation of haddock fillets for a period of 2 minutes produced definite bactericidal effect, and irradiation for a period of 2 hours was found to increase the vitamin D potency of the fillets. Further tests are being conducted to determine the extent to which this process may be applicable on a commercial scale by experiments on more species of fish under varying conditions and periods of irradiation.

### STUDIES IN THE HANDLING OF FRESH OYSTERS

As stated in last year's Divisional report, the purpose of this investigation is to develop and recommend improved methods for handling fresh oysters. When oysters are first shucked, the pH is nearly 7.0, indicating a neutral reaction of the flesh. During the first few days of storage, the pH rapidly decreases until a point of approximately 6.10 is reached. It then decreases much more slowly until it reaches a pH of 4.50. Below this point oysters become so sour that they are unfit for food. During this same period of change in the pH, the bacterial count declines to a minimum, after which it begins to rise rapidly as a result of the increased acidity of the oysters. The experiments also show that the bacterial flora changes with the acidity of the oysters. It was further found that excessive washing of the oysters with fresh water caused a loss of mineral content, in some cases from 1.50 percent to 0.18 percent.

#### STUDIES OF METHODS OF PREPARING CRAB MEAT

At the request of a group of crab-meat packers, funds were provided to this Bureau by Congress, effective July 1, 1938, for the purpose of making a chemical and bacteriological investigation of existing methods of preparing crab meat, in the hope that improvements in such methods could be recommended to the industry. The 6 months which have been devoted to this survey have been concerned largely with the bacteriological phases of the problem. Following a survey of equipment and methods used by the packers of crab meat in the Chesapeake Bay area, a temporary field laboratory was established at Crisfield, Md., in which bacteriological and chemical examinations of commercial samples of prepared crab meat were made for the purpose of making definite recommendations designed to improve handling practices.

As a result of a thorough study of the methods employed by the various crab-packing plants, several recommendations were made to the packers which should result in definite improvement of the product. A detailed report on the results obtained thus far in this investigation has been prepared and will be published in the near future.

#### PHARMACOLOGICAL STUDIES

As more has become known in recent years concerning the importance and significance of fishery products in the diet of man and his domestic animals, there has been an increasing demand for knowledge concerning the physiological effects of the different constituents of fishery products under the varying conditions under which they are manufactured and included in man's diet or in the rations of livestock. This particularly involves the metabolism of mineral constituents such as copper, arsenic, and fluorine. It also concerns studies of possible toxicity of products such as fish meal when improperly manufactured, or when decomposed due to careless conditions of handling after manufacture and before reaching the feed manufacturer or ultimate consumer.

# CHEMICAL AND PHARMACOLOGICAL STUDIES OF THE FLUORINE IN FISHERY PRODUCTS

As stated in the 1937 report of this Division, a high content of fluorine in the diet has been responsible for mottled enamel of teeth in both man and domestic animals. In cases where this difficulty has been particularly noticeable, the fluorine has been traced to mineral mixtures of inorganic origin incorporated in the diet. However, as a result of this difficulty, there has been a demand for more knowledge concerning the fluorine content of such food products as meat and fish and the physiological effect of fluorine from a natural food source as compared with fluorine of inorganic origin. Because of this situation, our technologists, in 1937, began chemical and pharmacological studies of fluorine in fishery products. Our work thus far has been confined to canned salmon and canned mackerel. Chemical analyses of the samples used in the tests showed a content of 5.8 parts per million of fluorine in the salmon on a fresh basis and 27

parts per million of fluorine in the mackerel under similar conditions. These samples, supplemented only by vitamin concentrates, were fed as the diet of albino rats in the Bureau's laboratories. No gross toxic effects were observed in any of the rats fed either species of fish during a test period of 12 weeks. However, an examination of the teeth of the experimental animals with a low power lens at the close of the test showed that the rats receiving the mackerel had developed fine white striations across the normal yellow of the enamel. None of the rats receiving the salmon showed any effects of striations and in no case was there any structural defect or abnormal growth of the teeth noted.

Analyses of the carcasses of the rats showed a close correlation between the amount of flourine ingested in the food and the amount stored in the body of the rat. Whether the source of fluorine was mackerel or salmon, approximately 20 percent of the ingested fluorine was stored in the body of the animal in most cases. The average amount of fluorine in the bodies of the rats at the close of the test was slightly over 18 parts per million for the groups fed salmon, and about 74 parts per million for those fed mackerel. The data show an inverse correlation between rat weight and the unit level of fluorine (in terms of parts per million). This was most marked where the variation in weight of the rats, within a group at the close of the test, was large. In other words, when the food intake and the rate of growth were below normal, a higher than normal percentage of the ingested fluorine was stored, and vice versa. These statistical or mathematical ratios, along with more detailed data, will be presented in a separate report to be published in the near future. it is well to point out here that, at the low levels of percentages of fluorine fed in the diet, a much higher percentage of the fluorine of inorganic origin added to the diet of the rat was stored in its body than was the case with the fluorine of inorganic origin.

### POSSIBLE TOXIC PROPERTIES OF CERTAIN FISH MEALS

Fish meals, as now produced on a commercial scale in the United States, are manufactured under a great variety of conditions and, therefore, differ considerably in composition and quality. variations are due to differences in chemical composition and relative freshness of the raw material from which the fish meal is made, differences in methods of manufacture and equipment used, and differences in conditions of handling, storage, and shipment. Furthermore. fish scrap or meal was originally produced in this country primarily for use as an ingredient of commercial fertilizers, and it has only been in recent years that the major portion of it has been used as an ingredient of mixed feeds and of livestock rations. Therefore, the transition of the industry from the old methods of processing, suitable for a product of a fertilizer grade, to improved methods of manufacture necessary to produce feed concentrates of quality has naturally been a gradual one. Consequently, in a situation as described above, Federal and State regulatory feed officials and chemists have encountered quite a problem in the equitable judging of quality of fish meals in connection with the administration of feed laws. Likewise,

feed manufacturers have expressed a desire for sufficient information to determine when a fish meal is suitable for animal feeding and when it is only of fertilizer grade. Since decomposition or spoilage of any food or feed product is a progressive change and a relative term, and since it is well known that some types of decomposition are not objectionable or harmful, there was a considerable demand from both producing and consuming industries interested in fish meal that the Bureau's technologists investigate the possible toxic properties of fish meals prepared from partially decomposed fish or under other adverse conditions of manufacture, handling, or storage.

Therefore, during 1938, chemical and pharmacological studies were inaugurated on this project. The fish meals used in these tests were menhaden, California sardine or pilchard, and so-called white fish meal prepared from trimmings of cod, haddock, and other ground fish. Good commercial meals of varying quality and experimentally spoiled meals were fed to groups of albino rats and baby chicks. no significant differences in gains in weight and food intakes of rats fed the commercial and the spoiled meals. Groups of chicks fed the spoiled meal in an otherwise purified diet generally grew faster and had a decreased mortality rate over groups fed the commercial meals. Apparently, conditions in the spoiled fish meals favored the bacterial synthesis of vitamin K and possibly of other vitamins required by the chicks. Data thus far indicate that the spoiled fish meal can be used to advantage as a protein supplement in any ration adequately balanced in vitamins and minerals.

#### MANUFACTURE OF FISHERY BYPRODUCTS

Studies in this field cover the utilization of the various byproducts of the fisheries and methods for testing and improving their quality.

#### UTILIZATION OF SALMON CANNERY TRIMMINGS

For the past several years the Bureau has devoted a portion of its technological activities to a study of the problem of utilizing salmon cannery waste. During this time a rather complete survey has been made regarding the nature and the composition of salmon waste, information has been obtained which fully demonstrated the value of salmon oils as sources of vitamins A and D, data have been obtained on the varied chemical and physical properties of these oils which may be expected to elucidate their utility in technical consumption, and assistance has been given the industry in developing an edible oil which can be added to the canned product. This line of attack has been followed because it was believed a better understanding of the nature and potential utility of salmon waste and the products available therefrom would stimulate a natural expansion in utilization.

However, due to the varied economic and technical obstacles prevailing throughout the salmon-canning industry, the general line of study outlined above could not be expected to be of definite help in all situations. Also, increasing utilization of waste material for the manufacture of edible canning oil has led to new problems regarding the best methods of converting the unused waste portions into their most valuable state. Therefore, after having provided a general background, attention is being directed to the development of methods which can be used in meeting specific situations prevailing in the

industry.

During 1938 studies have been made on the suitability of small-unit rendering equipment for small canneries not producing enough waste to warrant installation of standard fish-meal and oil machinery. Attention has been given to the response of salmon waste to dry rendering and the conditions necessary to retain the natural properties of the rendered oil. Studies have been undertaken regarding the preparation of dehydrated protein concentrates which would also serve as vitamin A and D concentrates.

In considering conditions where huge quantities of waste are accumulated during an extremely short operating period and where a reduction plant of large capacity would have to be idle over 10 months out of a year, studies have been undertaken regarding methods of chemical preservation and chemical treatment for conversion into entirely different type products which could be prepared with a minimum of equipment. However, because of the limited period during which salmon waste representative of commercial operations can be obtained, the data from these more specialized studies are as yet incomplete and no conclusions can be drawn. The last of a series of papers covering the general aspects of salmon byproducts has been published. This report is entitled, Investigational Report No. 40, "Pacific Salmon Oils."

The results show that the waste material or cannery trimmings of chinook salmon will yield between 30 and 40 gallons of oil per ton; Alaska and coho salmon, from 25 to 35 gallons; pink salmon trimmings, from 15 to 25 gallons; and chum salmon waste, from 10 to 15 gallons. Since between 80 and 90 percent of the total catch of salmon is canned and thus most of the waste material consisting of heads, tail portions, fins, and visceral organs are accumulated in connection with cannery operations, it can be readily seen that there is a large supply of waste material in the salmon canning industry from which oil may be manu-The survey further shows that about 30 percent of the round weight of chinook salmon is waste material, about 33 percent of Alaska red, coho, and chum salmon, and about 35 percent of pink salmon constitute waste material from which byproducts may be made. This report also contains tables showing the chemical and physical characteristics and properties of salmon oils such as iodine number, refractive index, specific gravity, etc. This information is of value in determining commercial uses for which the oils are best suited.

# STUDIES ON THE PEROXIDE TEST AS A MEASURE OF OXIDATIVE DETERIORATION OF FISH OIL

Oxidative deterioration of fatty fish is a gradual process which eventually manifests itself in rancid odors and flavors readily detected by organoleptic means. When such a condition has been reached, the product is definitely of poorer quality and less desirable as food. In investigations on fish spoilage, the preservation of fish by various methods, and in commercial handling of fish, it is highly desirable to have some measure of the progress of oxidative deterioration prior to the development of rancid flavors and odors, since the problem of marketing is to get a product into consumption before the odor and flavor is definitely affected.

Because of the importance of this problem to all food industries. numerous methods have been proposed for measuring or following the progress of incipient rancidity. One of the most popular tests is that predicated upon the assumption that peroxides are formed as an intermediate step in the development of rancid products and such peroxide compounds break down in the presence of potassium iodide with the liberation of iodine, which can be easily measured. However, when the test, as prescribed for other fatty materials, is applied to highly unsaturated fish oils, the results obtained are not entirely satisfactory. Data are frequently inconsistent and the values obtained appear to be affected by a number of factors which tend to decrease the sensitivity of measurement. In spite of these drawbacks, the method has considerable merit on account of its simplicity, the speed with which determinations can be made, and the fact that no complicated or expensive apparatus is required. Therefore, an investigation was undertaken to determine the possibility of improving the peroxide test so that it could be used as a more reliable tool in investigating oxidative deterioration in fishery products. progress of the work so far has been most encouraging. conditions of the reactions have been investigated and a modified procedure has been devised whereby a number of the drawbacks of other procedures are eliminated. The test, however, must be subjected to more rigorous examination before definite conclusions can be made. Should these studies result in a more effective measure of incipient rancidity, future investigations, both scientific and practical. on the handling and preservation of fatty fish will be greatly facilitated.

#### UTILIZATION OF FISH LIVERS AND VISCERAL ORGANS

The sustained commercial interest in sources of concentrated vitamins A and D has led to increasing demands upon the Bureau for information regarding the utilization of fish livers and visceral organs. In recent reports reference has been made regarding the development of methods for extracting oil or vitamins from various types of material which would not respond to normal treatment. As a result of the data obtained, the Bureau's technologists have been able to advise with the industry on extraction problems and have contributed materially to the expansion in vitamin oil manufacture.

During the past year attention has been directed to a general survey of the potential value of the liver and viscera from all types of food fish taken on the Pacific coast. Analyses for oil content and vitamin A potency have been made on periodic samples involving 22 different species of fish. The oil content of the livers from the species examined ranged from 1.5 to 35 percent and the vitamin A potency of the extracted oil varied from 6,000 to 380,000 units per gram. Viscera less liver and stomachs ranged in oil content from 0.3 to 45.3 percent and yielded oils having vitamin A potencies ranging from 4,500 to 450,000 units per gram. The data will be summarized for publication when the survey is completed.

## PREPARATION OF FISH MEALS OF IMPROVED NUTRITIONAL VALUE

The Bureau's interest in fish meal in animal feeding pertains to both terrestial and aquatic animals. During the year technologists of the Division have continued to cooperate with the Department of Poultry

Husbandry at the State College of Washington, the Bureau's Division of Fish Culture, and the School of Fisheries at the University of Wash-

ington.

Studies carried on by the Division of Fish Culture and the University of Washington in recent years have resulted in the preparation of a fish meal especially suitable for fish feeding. During the year technologists of the Division of Fishery Industries have cooperated in production studies in order to clarify the steps in preparation responsible for the improved nutritional properties and to determine means of obtaining the same feeding effectiveness by a simpler process of manufacture. The results indicate that the preservation of water-soluble, heat-sensitive extractives contributes to the improved feeding properties and this can be accomplished in simple dry rendering equipment operating under reduced pressure. The studies are being repeated, since the final conclusions may provide the basis for future fish-food plants to be installed by the Bureau and other agencies engaged in fish-cultural work.

#### STUDIES ON FAT IN FISH MEAL

This project was begun in 1937 and consists of collaborative work of various Government laboratories in the development and gradual improvement of methods of analysis sponsored and coordinated by the Association of Official Agricultural Chemists. Specifically, present studies involve methods of determining oil or fat in fish meal more accurately than existing methods permit. A progress report on the work was prepared and presented at the annual meeting of the Association of Official Agricultural Chemists in November 1938. The accuracy and efficiency of various chemical or organic solvents for determining the amount of oil or fat in fish-meal samples by solvent extraction were tested. Thus, this report contains a table showing the percentages of oil extracted by the various solvent reagents under differing conditions. These figures are of interest to the analytical chemist in determining the comparative accuracy of these solvents in making analyses of this kind.

#### CHEMICAL PRESERVATION OF FISH AND FISH WASTE

As described in the 1937 annual report of this Division, this project was established by the Bureau as a cooperative arrangement with the Aquacide Co., Washington, D. C., and the studies are being conducted by research associates employed by that company and stationed in the Bureau's laboratories. The work consists in the development and application of chemical compounds for preserving fish livers, cannery trimmings, scrap and other fish waste, either temporarily until these materials can be transported to a central point for further mechanical processing or reduction, or as a permanent preservative in a few instances. Most of the work in 1938 was devoted to the application of a chemical solution, developed by this company, to the preservation of dogfish livers landed at isolated points for subsequent shipment to central fish-oil rendering plants.

About 1,500 barrels of dogfish livers were preserved by treatment

About 1,500 barrels of dogfish livers were preserved by treatment with a formaldehyde-soda-ash compound, and, at the end of 9 months of storage, were found to be in good condition. The treated livers

were then extracted and the oil was still in good condition, containing approximately 2,000 international units of vitamin A per gram. However, this oil was too low in vitamin D content to be considered as a commercial source of this vitamin.

#### NUTRITIVE VALUE OF AQUATIC PRODUCTS

This has always been an important phase of our technological investigations because the relative nutritive value of the finished product is in most instances the true yardstick or measure of the value of a new method of processing or an improvement in existing methods in the industry For example, assuming that costs of production are equal in each case, if a new method of manufacturing fish meal, or a new method of freezing fish fillets, produces a finished product of better quality measured in terms of food value, then that is a true estimate of its worth or justification for its commercial application.

#### MINERAL CONSTITUENTS OF FISHERY PRODUCTS

In recent years, members of our technological staff have been making a detailed study of the mineral content of some of the more important commercial species of fish and shellfish. Although this work was interrupted by resignation of personnel, it is now completed and detailed data on the calcium, phosphorus, magnesium, iron, copper, and iodine content of the edible portion of various species of fish and shellfish have been published in Investigational Report No. 41, entitled "The Mineral Content of the Edible Portions of Some American Fisherv Products." Fish fillets are about equal to the muscle cuts of beef in mineral content, except that the fish greatly exceeds the meat in iodine content. Canned salmon contains about 15 times as much calcium, almost twice as much phosphorus, 20 times as much iodine, and approximately equal quantities of other minerals as beef round. Oysters, shrimp, and crab meat contain approximately half as much calcium, more than five times as much magnesium, and more phosphorus than an equal quantity of milk. In addition, these shellfish are a particularly good source of iron, copper, and iodine.

#### CHEMICAL COMPOSITION AND NUTRITIVE VALUE OF FISH PROTEINS

This study, begun several years ago, has now been completed. A report of the results of one phase of the project has been published in the scientific journal, Food Research, 1938, Volume 3, No. 5, under the title of "Nutritive Value for Growth of Some Proteins of Fishery Products." By using an arbitrary factor of 100, the proteins of the following fish and shellfish fell into groups according to relative growth-promoting value, as compared to beef at a factor of 63: Oyster 100; pilchard, red snapper, shrimp and Boston mackerel 90; and shad, cod, croaker, and silver salmon 80.

The chemical determinations of the principal amino acids in the proteins of several species of fish and shellfish have also been completed and a report is now being prepared for publication. Arginine, histidine, and lysine were determined in the proteins of 20 species of fish and shellfish as follows: Cod, croaker, haddock, halibut, sea herring, lake trout, Boston mackerel, Spanish mackerel, mullet, pilchard,

red snapper, chum salmon, king salmon, silver salmon, shad, squeteague, hard clam, blue crab, oyster, and shrimp. Tryptophane was determined in the proteins of 28 species as follows: Catfish, cod, croaker haddock, halibut, lake herring, sea herring, lake trout, Boston mackerel, Spanish mackerel, mullet, pilchard, red snapper, chum salmon, king salmon, pink salmon, silver salmon, sockeye salmon, shad, squeteague, albacore tuna, bluefin tuna, bonito, skipjack, hard clam, blue crab, oyster, and shrimp. Cystine was determined in the proteins of the following 13 species: Cod, croaker, haddock, halibut, Boston mackerel, Spanish mackerel, mullet, red snapper, king salmon, pink salmon, silver salmon, shad, and shrimp.

## VITAMIN CONTENT OF FISHERY PRODUCTS

The only work done on this subject in 1938 was a series of assays of the vitamin D content of experimentally prepared fish-liver oils forwarded by our Seattle laboratory, in connection with its byproducts studies, to our nutrition laboratory at College Park. These determinations were used as a method of evaluating various methods of handling and extracting fish livers and are discussed in Investigational Report No. 40, entitled "Pacific Salmon Oils," previously discussed in this report.

## SODIUM ALGINATE AS A STABILIZER IN PRODUCTS OF THE DAIRY INDUSTRY

Sodium alginate is a very useful preparation produced from the giant kelp (Macrocystis pyrifera) harvested from waters on the Pacific coast. It is used extensively as a stabilizer in such dairy products as chocolate milk, ice cream, etc. The results have been very satisfactory to the dairy industry from the mechanical standpoint, but regulatory authorities have expressed a desire to learn whether sodium alginate has any toxic properties. Accordingly, two commercial samples of sodium alginate were used in feeding tests with experimental animals and were tested in the diet in percentages much higher than would be used as a stabilizer in dairy products. The results of these experiments showed no indications whatsoever of any toxicity of the sodium alginate. The detailed conclusions of this study have been assembled in a report.

KELP MEAL IN ANIMAL FEEDING

This project was inaugurated several years ago by the Dairy Department of the University of Maryland and of the Maryland State Agricultural Experiment Station at College Park, Md., in cooperation with our technologists, to determine whether kelp meal, as a mineral supplement, had value in improving reproduction in dairy cattle. The tests thus far have been conducted with heifers and the preliminary results have been very encouraging. The study is being continued with producing or lactating dairy cows on a more extensive scale and it is hoped that information of considerable interest and benefit to the dairy industry will result from these experiments. Tests of this kind with large farm animals, such as dairy cows, require several years for the production of conclusive results. However, quite definite improvement in the reproductive record of the animals fed kelp meal has resulted thus far.

#### RESEARCH ASSOCIATES AND STUDENT ASSISTANTS

Because of the relatively small size of the Bureau's technological staff, and the rather broad field of research it must cover, it is only possible to undertake those problems which are of a fundamental nature and which promise to be of the greatest value to the largest number of persons, whose livelihood depends in whole or in part on the fisheries, and which are possible with the funds and personnel available. For this reason the Division cannot, with present facilities, attack problems of special or restricted interest affecting certain products. processes, methods, or industries. However, the Bureau has available, by congressional authorization and under an arrangement similar to that of other scientific Government bureaus, facilities for research associates and student assistants in its laboratories. and expenses of these employees are paid by the firms or groups who are interested in the problems on which they are working and the investigations are carried out under the supervision of the Bureau's technologists in its laboratories and under its control. Thus the Bureau provides these industries and groups with laboratory, consulting, and library facilities which, in most instances, cannot be obtained elsewhere.

Within the limits of its facilities, the Bureau also has opened its technological laboratories to research students who are pursuing courses in universities and who are selecting investigational problems in the fisheries as their major study. This may prove of special benefit to the industry as it brings its problems to the attention of a large group of research workers who in turn may spread interest to applied fishery research.

In the preceding sections of this report we have given the names of organizations which are conducting cooperative projects under the supervision of our technological staff and which have employed research associates for this purpose. In the preceding section on laboratories, we have given the individual names of these research associates and student assistants. The plan of utilizing graduate student assistants for working part-time on research projects has been so successful that the University of Maryland employed from its own funds additional graduate students, by establishing two research fellowships for work on fishery technological research. Some of these new research problems assigned to these research fellows at the beginning of the school year in October 1938, are: (1) Studies on the enzymes in fresh and frozen fish; (2) chemical and pharmacological studies on the oxidized oils in fish meals; (3) chemical and pharmacological studies on the decomposition of protein in fish meals; and (4) studies of certain bacterial enzymes responsible for certain types of fish spoilage. These projects are selected by the student in accordance with his qualifications, approved by both the Bureau and the University, and the results are prepared in a thesis submitted for a master's or a doctor's degree at the end of 3 years of part-time work. These students usually do excellent work, the results of such studies are usually of value to the industry, and this plan serves to educate and train scientific fishery investigators.

#### EDUCATIONAL AND CONSULTING SERVICE

In addition to the research activities described in this report, our economic and technological staffs conduct, along with their regular duties, an educational and consulting service for those interested in the fisheries. During the past year the demand for this type of service has increased. Many requests have been received from groups and individuals to demonstrate improved methods developed in our laboratories for the handling and processing of fishery products, for instruction in fish cookery, and for aid in improving various marketing practices. Insofar as our facilities have permitted, we have complied with these requests, endeavoring to offer assistance especially where the request has come from a large group or industry. However, we have not been able to comply with all of the requests received because of insufficient personnel and because of inadequate funds to provide for the travel expenses of the demonstrators.

Some of the educational services rendered are discussed or referred to in previous paragraphs of this report. In brief, this work has covered the fields of commercial preserving of fishery products, fish cook-

ery in the home, and the marketing of aquatic products.

Another phase of this service has consisted of answering thousands of letters directed to the Bureau on fishery subjects and of supplying information to persons who have called at the Bureau personally. Many of the latter came from foreign lands to seek fishery information which might be useful in the conduct of the industry in their native country.

#### PUBLICATIONS OF THE DIVISION

During the calendar year 1938 the following publications were prepared and addresses delivered by members of the Division's staff. These do not include the monthly statistical bulletins of the landings of fishery products at Boston and Gloucester, Mass., Portland, Maine, and Scattle, Wash., nor the monthly reports on cold-storage holdings of frozen fish and quantities of fish frozen. The fishery reports and circulars may be purchased, at the prices shown, from the Superintendent of Documents, Government Printing Office, Washington, D. C. The statistical bulletins and special or S-memoranda are distributed free of charge upon request to the Bureau. The special articles may

be obtained from the sources of publication.

Those wishing to receive copies of this report and statistical bulletins as issued should request that their names be placed on the Bureau's mailing lists, Nos. 128 for the annual statistical report; 128a for general statistical bulletins; 128b for monthly cold-storage reports; and 128d for periodic fishery market news reports. Those desiring daily fishery market news reports from any one of the Division's Fishery Market News offices which have been established should apply direct to the Bureau of Fisheries, Division of Fishery Industries, Fishery Market News Service at the nearest of the following five addresses: 33A Fulton Street, New York, N. Y.; 253½ Northern Avenue, Boston, Mass.; 200 North Jefferson Street, Chicago, Ill.; 309 Duval Building, Jacksonville, Fla.; or 421 Bell Street Terminal, Seattle, Wash. For historical statistical data on the domestic fish-

eries for the period 1880 to 1929 consult the report entitled "Fishery Industries of the United States, 1930," by R. H. Fiedler, appendix II to the report of the United States Commissioner of Fisheries for the fiscal year 1931. Statistical information for the years 1930 to 1936, inclusive, may be obtained from the annual reports of the Division for the years 1931 to 1937, inclusive.

## Part 2. FISHERY STATISTICS, 1937

#### GENERAL REVIEW

Available statistics indicate that there was a decrease in the volume but an increase in the value of fishery products taken in the United States and Alaska during 1937, as compared with the preceding year. Data on the catch were collected for both 1936 and 1937 in the Chesapeake, South Atlantic and Gulf, Pacific, and Lake States, and in Alaska. The combined catch in these sections alone shows a decrease of 13 percent in volume but an increase of 7 percent in value. Decreased catches were made in each of the five geographical sections; however, the principal reductions occurred in the Pacific Coast States where greatly reduced catches of pilchards were taken, and in Alaska where there was a large decline in the catch of salmon. The value of the production of canned fishery products in all sections increased 11 percent as compared with 1936; byproducts increased 5 percent; frozen fish about 1 percent; and packaged fish 3 percent.

The total catch of fishery products in the United States and Alaska, as based on the most recent surveys, amounted to 4,352,549,000 pounds, valued at \$100,845,000. About 130,000 fishermen were

employed in making this catch.

The production of canned fishery products in the United States and Alaska during 1937 amounted to 742,197,065 pounds, valued at \$105,174,935; the output of byproducts was valued at \$36,804,045; the production of frozen fishery products, excluding packaged products, amounted to 103,111,549 pounds, estimated to be valued at \$8,800,000; and fresh and frozen packaged fish and shellfish, 201,802,529 pounds, valued at \$27,677,899. Based on surveys for 1937 in all sections except the Mississippi River area, and for 1931 in that area, the production of cured fishery products amounted to 104,339,340 pounds, valued at \$15,635,280. It is estimated that about 686,000,000 pounds of fresh fishery products (excluding packaged fish and shellfish) valued at about \$57,000,000, were marketed during 1937. The total marketed value to domestic primary handlers of all fishery products in 1937 is estimated at \$251,000,000.

Fishery products imported for consumption were valued at

\$50,635,515 and domestic exports were valued at \$14,567,252.

New England States.—In 1937 the commercial catch of fishery products in these States showed an increase in both volume and value as compared with 1935, when the first preceding survey of the total catch of these States was made. The yield of the fisheries in this section during 1937 was the largest that has been recorded, with the exception of the catch for the years of 1929 and 1930.

A comparison of the combined vessel landings at Boston and Gloucester, Mass., and Portland, Maine, which are available for both 1936 and 1937, show that those landings declined in 1937.

Middle Atlantic States.—The 1937 commercial catch of fishery products in the Middle Atlantic States decreased in volume but increased

in value as compared with 1935, when the first preceding survey of the total catch was made. Available data for both 1936 and 1937 show that the production of frozen fish in these States declined in 1937, while the catch of shad in the Hudson River was the largest on record since 1901.

Chesapeake Bay States.—In 1936 the catch of fishery products in the Chesapeake Bay States decreased in both volume and value, as compared with the previous year. The value of menhaden products, which were produced in Virginia, declined during the year, while both the quantity and value of fresh-shucked oysters, and

packaged fresh-cooked crab meat increased.

South Atlantic and Gulf States.—The catch of fishery products in the South Atlantic and Gulf States during 1937 declined in volume but increased in value, as compared with the previous year. There was a large increase in the value of manufactured fishery products produced in these States in 1937 due to material increases in the production of packaged fresh-cooked crab meat, fresh-shucked oysters, and canned shrimp and oysters.

Pacific Coast States.—The commercial catch of fishery products in these States during 1937 decreased in volume, but increased in value. The decrease in volume resulted principally from reduced catches of pilchards in California. The 1937 production of canned sardines, salmon, and tuna increased as compared with 1936, while the packs of mackerel and oysters decreased. The value of fishery byproducts,

which consist largely of fish meal and oil also declined.

Lake States.—In 1937 the commercial catch of fishery products in the Lake States decreased in both volume and value, as compared with 1936. The decreases resulted principally from reduced catches of

blue pike.

Mississippi River and tributaries.—The most recent complete statistics of the catch of the Mississippi River and tributaries are those collected for 1931. As compared with 1922, when the most recent preceding survey was made, there was a decrease in the catch. This decrease was reflected principally in a smaller catch of fresh-water mussels. A survey made for Lakes Pepin and Keokuk, and the Mississippi River between these two lakes, for 1937 showed a decrease in the catch of fishery products in Lake Pepin and the Mississippi River between these lakes, but an increase in the catch in Lake Keokuk as compared with the previous year. The production of fresh-water mussel-shell buttons declined in 1937 as compared with 1936.

Alaska.—The catch of fishery products in Alaska in 1937 decreased in volume but increased in value, as compared with 1936. There was a material decline in the yield of salmon for the year, while the catches of herring and crabs increased. The production of frozen fishery products and byproducts increased in quantity and value in 1937, while the output of fresh, cured, and canned products decreased.

#### Fisheries of the United States and Alaska, 1937 1

#### SUMMARY OF CATCH: By sections

[Expressed in thousands of pounds and thousands of dollars; that is, 000 omitted]

Product	New E			e Atlantic XXIII	Chesar area X		and	Gul	tlantic fareas and V	Pac	ific

⁷ The weight of whales caught was not determined; therefore, the weight of manufactured products is shown. This tabulation does not include data on the whale fishery, conducted by United States enterprise in the Southern Hemisphere. For data on this fishery, the reader is referred to the following sections of this report: "Manufactured Fishery Products," "Canned Fishery Products and Byproducts Trade," the manufactured products table in the section entitled "Middle Atlantic States," and to the section entitled "Whaling."

The weight of whales caught was not determined; therefore, the weight of manufactured products is shown. This tabulation does not include data on the whale fishery, conducted by United States enterprise in the Southern Hemisphere. For data on this fishery, the reader is referred to the following sections of this report: "Manufactured Fishery Products," "Canned Fishery Products and Byproducts Trade," the manufactured products table in the section entitled "Middle Atlantic States," and to the section entitled "Whaling."

Includes Lake Ontario, Lake Erie, Lake Huron, Lake Michigan, Lake Superior, Rainy Lake, Namakan Lake, Lake of the Woods, Lake Okeechobee, and several mus el-bearing streams tributary to Lakes Huron, Erie, and Michigan.

Data are for 1937 except that for Mississippi River and tributaries which are for 1931.
 Includes the catch by drop nets and wire baskets.
 This catch was made by scoop nets.
 Includes a small catch by other trawls.
 The catch by shovels, rakes, and dredges is included with tongs.

#### MANUFACTURED FISHERY PRODUCTS

The output of manufactured fishery products (canned, cured, packaged, and byproducts) in the United States and Alaska during the most recent years for which data are available was valued at \$185,292,159. Of this amount, canned products accounted for 57 percent, byproducts 20 percent, fresh and frozen packaged products 15 percent, and cured products 8 percent.

Since complete general statistical surveys were conducted for 1937 data in each of the geographical sections of the United States and Alaska except the Mississippi River area, the following compilation of manufactured fishery products consists of data for 1937 with the exception of a small quantity of salted and smoked fish produced in the Mississippi River section.

Includes soows, houseboats, pile drivers, etc.
 Statistics not available.

Note.—Of the total number of persons engaged in the preparation of fishermen's manufactured products 5.574 have also been included as fishermen, and 1.509 of the persons shown on transporting craft have also been included as fishermen.

1 All data are for 1937 except for a small quantity of salted and smoked fish produced in the Mississippi River section which are for 1931. 1 This is usually an intermediate product and although shown in the total may also be shown in its final stage of processing elsewhere in the table.

Data are for 1937 and 1931.

Data are for 1931.

Data are for 1931.

I Data are for 1931.

Includes the production of both edible and industrial salmon oils.

Includes fresh fillets of carp, red drum, kingfish or "king mackerel," mullet, muttonfish, sea robin, snook or sergeantfish, striped bass, and suckers.

snook or sergeantfish, striped bass, and suckers.

7 Includes frozen fillets of bluefish, croaker, halibut, king whiting or "kingfish," lake trout, "lingcod," Spanish mackerel, spot, and squeteagues or "sea trout."

§ Includes fresh pan-dressed red drum, Spanish mackerel, and whiting.

§ Includes fresh steaks of cablo, cod, haddock, halibut, mackerel, pollock, and snook or sergeantfish; frozen steaks of cod, pollock, and wolffish; and fresh sticks of whiting.

10 Includes salted barracuda, haddock, lake trout, pilchard, black and white sea bass, tenpounder, tuna, yellowtail, fillets of cod, hake, and Spanish mackerel, boneless cusks; king whiting or "kingfish" roe, and salmon bellies; spiced anchovies, chub, mackerel, and oyster and shrimp cocktail; pickled eels, and sea-herring roe. sea-herring roe.

11 Includes smoked goldeye, hake, scup or porgy, miscellaneous fish, and fillets of haddock, hake, sea

"Includes smoked galacye, make, scap of polgy, instance, and pollock."

Includes canned saited cod, pickled eels, finnan haddie, kippered sturgeon, tuna roe, fish bouillon, soft crabs, spiny lobster or "sea crawfish" soup, shrimp soup, hard-clam stew, razor-clam juice, soft-clam cakes, oquina clam broth, pickled sea mussels, squid, frog products, deep-sea roe, rat poison bait, and crab and shrimp gumbo.

13 Includes shark and miscellaneous dry scrap; alewife acid scrap; and sea herring and miscellaneous

green scrap.

1 Includes salmon-egg, shark, soft-clam, starfish, cod-liver, and miscellaneous fish meals.

1 Includes burbot, halibut, sablefish, shark, swordfish, and tuna liver oils.

1 Includes blackfish, rosefish, and miscellaneous fish oils.

1 Includes blackfish, rosefish, and miscellaneous fish oils.

1 Includes isinglass, kelp products, pearl essence, clam-sholl lime, miscellaneous novelties, and freshwater mussel-shell novelties, stucco, and chips.

Note.—Some of the above products have been manufactured from raw products imported from another country; therefore, they cannot be correlated directly with the catch within the United States and Alaska.

#### CANNED FISHERY PRODUCTS AND BYPRODUCTS TRADE

The output of canned fishery products and byproducts in the United States and Alaska in 1937 was valued at \$141,978,980. Of this total, canned products comprised \$105,174,935, and byproducts, \$36,804,045—an increase of 11 percent in the value of canned products and 5 percent in the value of byproducts when compared with the respective values of the same groups of commodities for the previous year.

Fishery products were canned at 405 establishments in the United States and Alaska during 1937. The combined output of these canneries amounted to 19,530,809 standard cases. The net weight of

the products canned amounted to 742,197,065 pounds.

Canned fishery products or byproducts were prepared in 26 States and in Alaska during 1937. Alaska ranked first in the value of the products, accounting for 34 percent of the total, and California ranked second, with 29 percent.

laneous novelties.

Note,—The whale products shown for the Atlantic and Gulf coasts were produced on factory ships operating in the Southern Hamisphere.

Includes the production of burbot-liver oil in Minnesota and Wisconsin.
 Includes shark and miscellaneous dry scrap, as well as the production of miscellaneous acid scrap by

ii Includes shark and miscellaneous dry scrap, as wen as the production of miscellaneous meals and cod-liver pressings.
 ii Includes salmon-egg, shark, starfish, clam, and miscellaneous meals and cod-liver pressings.
 ii Includes a considerable quantity of salmon oil especially prepared for human consumption.
 ii Includes burbot-, balibut-, sablefish-, shark-, swordfish-, and tuna-liver oils.
 ii Includes blackfish, rosefish, and miscellaneous fish oils.
 ii A quantity of liquid glue produced by 1 firm in California is included with the production of liquid glue on the Atlantic and Gulf coasts.
 ii Includes herring and miscellaneous green scrap, isinglass, kelp products, pearl essence, and miscellaneous prosities.

### FROZEN-FISH TRADE 3

### FISH, FROZEN

During 1937 the output of freezing plants which reported their activities to the Government amounted to 168,223,653 pounds of fishery products. At the time these products were held in coldstorage plants they were estimated to be valued at about \$13,500,000. Compared with the output in 1936, this is a decrease of 6 percent in volume. Five species or groups of species accounted for 60 percent of the total amount frozen. In the order of their importance, they were: Cod, haddock, hake, and pollock (including cod, haddock, and pollock fillets), which accounted for 22 percent of the total; whiting, 11 percent; salmon, 10 percent; halibut, 9 percent; and rosefish, 8 percent. Other products frozen in considerable quantity during the year were mackerel, sablefish, and shellfish.

Production of frozen fishery products, 1937

### **HOLDINGS**

During 1937 monthly holdings of frozen fish and shellfish averaged 63,810,000 pounds, which is an increase of 3 percent as compared with 1936. The holdings during January were the largest, amounting to 87,576,000 pounds. In only two other months did the holdings exceed 75,000,000 pounds. These were November and December. The holdings were the smallest during May, when only 40,589,000 pounds of fishery products were in storage.

¹ New England includes the 6 States of that section; Middle Atlantic—New York, New Jersey, and Pennsylvania; South Atlantic—Delaware, Maryland, District of Columbia, Virginia, West Virginia, North Carolina, South Carolina, Georgia, and Florida; North Central, East—Ohio, Indiana, Illinois, Michigan, and Wisconsin; North Central, West—Minnesota, Iowa, Missouri, North Dakota, South Dakota, Nebraska, and Kansas; South Central—Kentucky, Tennessee, Alabama, Mississippi, Louisiana, Texas, Oklahoma, and Arkansas; and Pacific—Washington, Oregon, California, and Alaska.

² Includes a small amount of fish held in Colorado in the Mountain section.

# COLD-STORAGE HOLDINGS OF CURED FISH

During 1937 monthly cold-storage holdings of cured herring and mild-cured salmon averaged 22,918,000 pounds, which is an increase of 7 percent as compared with the average monthly holdings in 1936. The holdings during January were the largest, amounting to 26,097,617 pounds, and the smallest were in December, amounting to 17,299,938 pounds.

# FOREIGN FISHERY TRADE

The foreign trade in fishery products of the United States in 1937 amounted to \$65,202,767, of which \$50,635,515 represents the value of these products imported for consumption, and \$14,567,252, the value of exports of domestic fishery products. Compared with the previous year, there was an increase of 18 percent in total trade, 21 percent in the value of the imports, and 10 percent in the value of exports.

Imports consisted of 364,668,145 pounds of edible products, valued at \$33,910,738, and nonedible products, valued at \$16,724,777. Fishery exports consisted of 119,067,718 pounds of edible products, valued at \$13,729,441, and nonedible products, valued at \$837,811.

Import duties levied on fishery products imported during 1937 totaled \$8,253,677.

# FISHERIES OF THE NEW ENGLAND STATES

(Area XXII) 4

The yield of the commercial fisheries of the New England States (Maine, New Hampshire, Massachusetts, Rhode Island, and Connecticut) during 1937 amounted to 670,864,300 pounds, valued at \$19,937,288 to the fishermen, representing an increase of 2 percent in volume and 11 percent in value as compared with the catch in 1935, the most recent previous year for which catch statistics are available. These fisheries gave employment to 19,624 fishermen, as compared with 18,449 in 1935.

There were 400 fishery wholesale and manufacturing establishments in the 5 States in 1937, as compared with 380 in 1935 when the most recent survey of these establishments was made. In 1937 these establishments employed 12,122 persons, paid \$7,705,479 in salaries and wages, and produced manufactured products (canned, cured, packaged, and byproducts) valued at \$24,038,947. In 1935 the wholesale and manufacturing firms employed 10,561 persons, paid \$6,456,456 in salaries and wages, and produced manufactured products valued at \$22,838,942.

⁴ This is the number given this area by the North American Council on Fishery Investigations. It should be explained that there are included under this area craft whose principal fishing ports are in the area but at times fish elsewhere. Notable examples are the groundfish fishery in area XXI and the mackerel and southern trawl fisheries in area XXIII. For a clearer understanding of the statistics published in this section, the reader is referred to the section in the latter part of this document entitled "Statistical survey procedure."

- A small quantity of manufactured products produced in New Hampshire have been included with those of Maine.
- This item has been included under "Unclassified products."
  This item is usually an intermediate product, and although included in the total, may be shown in its final stage of processing in this or another State.
- Includes the New Hampshire production.
- Includes fresh fillets of rosefish, and frozen fillets of cod, cusk, haddock, hake, and rosefish.
- Includes fresh fillets of halibut, red snapper, striped bass, and wolffish; and frozen fillets of halibut and salmon.
- Includes fresh steaks of cod, haddock, mackerel, halibut, pollock, salmon, and swordfish; frozen steaks of cod, halibut, wolffish, pollock, salmon, and swordfish; and fresh whiting
  - 4 The production of this item has been included under "Miscellaneous."
  - Includes salted fillets of cod and hake; green-salted cusk and haddock; dry-salted pollock and haddock, salted boneless hake; and pickled and spiced alewives.
  - 10 Includes smoked fillets of hake, herring, and pollock.
  - 11 Includes smoked fillets of haddock and hake; smoked alewives, butterfish, carp, herring, and herring bloaters, lake trout, mackerel, salmon, shad, and whitefish.
  - 12 This item has been included under "Other canned products."
  - 13 Includes canned finnan haddie, alewife roe, clam cakes, fish chowder, and fish flakes.
  - 14 Includes canned tuna, mackerel, clam products, finnan haddie, haddock chowder, and miscellaneous canned groundfish products.
  - 15 Includes rosefish, blackfish, and cod oils.
  - 14 Includes tuna, halibut, sablefish, swordfish, and mixed liver oils.
- Includes fresh-cooked lobster meat; salted boneless cusk; green-salted haddock; herring scrap and meal; groundfish, clam, and miscellaneous fish meals; marine-shell buttons; pearl essence; and kelp products.
  - 18 Includes fresh-shucked clams and scallops; herring pickled in vinegar; miscellaneous scrap and meal; liver pressings; glue; isinglass; and marine-shell products.
  - 11 Includes fresh-cooked crab and lobster meat; smoked finnan haddie; canned hard clam chowder; and marine-shell products.
- " Includes smoked butterfish, carp, chub, cisco, salmon and spoonbill cat; and poultry feed from crushed marine-shells.

NOTE .-- The total value of manufactured products for the New England States was as follows: By manufacturing establishments, \$24,038,947; and by fishermen, \$1,098,993. Some of the above products may have been manufactured from products imported from another State or a foreign country; therefore they cannot be correlated directly with the catch within the State. Of the total number of persons engaged in the preparation of fishermen's manufactured products, 3,371 have also been included as fishermen, and 16 of the persons shown on transporting craft have also been included as ashermen. This should be considered when computing the total number of persons in the fishery industries exclusive of duplication.

Note —Of the total number of persons fishing for seed oysters, 217 are duplicated among those fishing for market cysters or other species. Similarly the following craft and gear are duplicated: 7 vessels, 1 motorboat, 53 other boats, and 14 dredges.

### VESSEL FISHERIES AT PRINCIPAL NEW ENGLAND PORTS

Due to the importance of the ports of Boston and Gloucester, Mass., and Portland, Maine, as landing points for fishery products, detailed monthly statistics are collected for these landings which are published in the following section:

#### ECONOMIC ASPECT

The landings of fishery products at the three principal New England ports (Boston and Gloucester, Mass., and Portland, Maine) by vessels of 5 net tons capacity or more during 1937, amounted to 387,960,010 pounds as landed, valued at \$9,789,879. This is a decrease of 6 percent in the quantity of the catch as compared with 1936, and also a decrease of 12 percent in the value of the catch. The landings at Boston accounted for 324,599,527 pounds valued at \$8,467,985, or 84 percent of the total volume; the landings at Gloucester amounted to 46,238,971 pounds valued at \$918,008, or 12 percent of the total; and the landings at Portland amounted to 17,121,512 pounds, valued at \$403,886, or 4 percent of the total.

Among the landings of fresh fish, haddock far outranked other species in volume landed. Landings of all sizes of haddock in 1937 amounted to 137,175,269 pounds, or 35 percent of the total fresh fish.

Note.—The weights of fresh and salted fish given in these statistics represent the fish as landed from the vessels, and the values are those received by the fishermen. Large cod are classified as those weighing over 10 pounds; market cod, 2½ to 10 pounds; and scrod cod, 1 to 2½ pounds. Large haddock are those weighing over 2½ pounds and sorod haddock, 1 to 2½ pounds. Large hake are those weighing over 6 pounds and small hake, under 6 pounds. Only landings by vessels having a capacity of 5 net tons or greater are used in this tabulation. Prior to Jan. 1, 1937, statistics were not collected separately on the individual species of flounders.

The items under "Other, fresh" include albacore, 35 pounds, value \$2; alewives, 109,415 pounds, value \$1,120; butterfish, 122,831 pounds, value \$6,904; cunner (perch) 320 pounds, value \$11; eels, 1,790 pounds, value \$45; goosefish, 16,525 pounds, value, \$178; herring smelt, 10,615 pounds, value \$191; salmon, 83 pounds, value \$19; scup or porgy, 15,030 pounds, value \$141; sea bass, 640 pounds, value \$25; shad, 30,409 pounds, value \$1,769; sharks, 65,356 pounds, value \$1,865; skates, 34,822 pounds, value \$460; striped bass, 28,185 pounds, value \$2,536; sturgeon, 3,633 pounds, value \$350; tautog, 700 pounds, value \$47; toun, 119,619 pounds, value \$5,875; mixed fish, 8,106 pounds, value \$127; lobsters, 251 pounds, value \$60; scallops, 8,752 pounds, value \$1,147; shrimp, 7,072 pounds, value \$502; and squid, 75 pounds, value \$1. The total for "Other, fresh" for 1937 does not represent the aggregate of "Other fresh" as recorded in the monthly bulletins throughout the year, since no livers, spawn, or tongues are included in the above table. These commodities were included in the monthly

¹ Does not include the landings of livers, sounds, spawn, and tongues previously reported in this item.

Note.—In addition to the above the following also were landed during 1937: Livers, 2,920,873 pounds, value \$65,669; spawn, 167,688 pounds, value \$6,466; and tongues, 30 pounds, value \$1.

#### BIOLOGICAL ASPECT

In 1937 the fishing fleet landing fares at Boston and Gloucester, Mass., and Portland, Maine, and operating on the fishing banks of the North Atlantic, numbered 373 steam, motor, and sail vessels of 5 net tons capacity or greater, as measured by the United States Customs Service. The catch of edible fish landed at the three ports amounted to 389,228,243 pounds when the salted fish had been converted to the basis of fresh gutted or round fish as usually landed. This, however, does not represent the entire catch of edible fish of these vessels, for landings were also made at ports in New England other than these three, at New York City, and at more southern ports in connection with the southern winter trawl and mackerel fisheries.

Otter trawls on all sizes of vessels accounted for 316,631,906 pounds, or 81 percent of the total landings. Line trawls were next in importance, accounting for 44,006,603 pounds, or 11 percent of the total

landings.

The catch taken off New England and landed at the three ports amounted to 237,283,835 pounds, or 61 percent of the total; that off Nova Scotia 146,965,720 pounds, or 38 percent; off the east coast of Newfoundland 3,818,780 pounds, or 1 percent; and that off the Middle Atlantic States 1,159,908 pounds, or less than one-half of 1 percent.

¹ Exclusive of duplication.

Note.—The 3 principal New England ports are Boston and Gloucester, Mass., and Portland, Maine. Otter trawls are classified according to the size of the vessel. The weight of salted fish landed has been converted to the equivalent of fresh fish as landed. Only landings by vessels having a capacity of 5 net tons or greater are used in this tabulation. "Occasional" after the name of a bank or ground indicates that the vessel or vessels contributing to the catch as shown fished chiefly with another type of gear. In such cases the number of vessels fishing, number of trips, and number of days absent, are shown under the principal type of gear used. The statistics of landings shown in this bulletin do not correspond exactly with the total of the 12 monthly bulletins since some of the monthly figures have been revised.

^{*} Incidental catch.

Note.—The weight of salted fish landed has been converted to the equivalent of fresh fish as landed. The roman numerals appearing in the stub of the above table refunders given these regions by the North American Council on Fishery Investigations.

#### MACKEREL FISHERY OF THE ATLANTIC COAST 5

The mackerel season of 1937 extended from April 12, 1937, to January 13, 1938. Ninety-six vessels landed 13,997,200 pounds, which represents a decrease of 65 percent as compared with corresponding landings of the preceding year.

landings of the preceding year.

Of the total landings, about 1,000,000 pounds were tinkers (fish under 1 pound) while the remainder were of larger sizes. The tinkers

were caught between July 1 and October 31.

The fishery was unusual because of its small yield (one of the lowest since the fishery began) and the comparative failure of the Gulf of Maine region. The season was unique in that it was the first to extend

into January.

In this analysis, vessels include United States craft of 5 net tons capacity or over. Vessels are classed as "regular" and "miscellaneous" on the basis of their effort throughout the whole mackerel season. Regular seiners fished in all three major areas and were active for more than two-thirds the duration of the Gulf of Maine fishery. Miscellaneous seiners are those who did not fish in the Southern area, or ceased seining activity for three months or more during the time of Gulf of Maine fishery. All netters are considered miscellaneous, inasmuch as each one enters the mackerel fishery for only a portion of the year. Craft using purse seines may change gear and engage in netting for a portion of the season, and during this time are classed as netters. Allowance for such duplication has been made in the summary "Operating Units and Catch."

Division of the whole mackerel season into three periods is determined by the gill-net fishery. The end of the early netting season terminates the period "Spring." Resumption of netting in the fall marks the beginning of the period "Fall and Winter." "Summer" is

included between these two periods.

1 Includes the catch made between Jan. 1 and 15, 1938.

^{*}This section, prepared by J. R. Webster of the Division of Scientific Inquiry, includes landings at Cape May and Wildwood, N. J.; New York, N. Y.; Newport and Block Island, R. I.; New Bedford, Buzzards Bay (Cape Cod Canal), Provincetown, Plymouth, Boston, and Gloucester, Mass.; and Portland, Maine; by purse-scine vessels or "seiners" and drift-gill-net vessels or "netters". It does not include incidental catches by other vessels such as menhaden seiners, otter trawlers, line trawlers, etc., or by traps.

## FISHERIES OF THE MIDDLE ATLANTIC STATES

(Area XXIII)6

The yield of the commercial fisheries of the Middle Atlantic States (New York, New Jersey, Pennsylvania, and Delaware) during 1937 amounted to 264,651,900 pounds, valued at \$7,895,990 to the fishermen, representing a decrease of 5 percent in volume but an increase of 23 percent in value as compared with the catch in 1935, the most recent previous year for which catch statistics are available. These fisheries gave employment to 7,720 fishermen, as compared with 9.620 in 1935.

There were 419 fishery wholesale and manufacturing establishments in the 4 States in 1937 as compared with 408 in 1935 when the most recent previous survey was made. In 1937 these establishments employed 6,839 persons, paid \$8,611,693 in salaries and wages, and produced manufactured products (canned, cured, packaged, and byproducts), valued at \$18,658,605. In 1935 the wholesale and manufacturing firms employed 6,143 persons, paid \$6,666,507 in salaries and wages, and produced manufactured products valued at \$13,441,812.

This is the number given to this area by the North American Council on Fishery Investigations. It should be explained that there are included in this area craft whose principal fishing ports are in the area but at times fish elsewhere. A notable example is the southern trawl fishery which extends into area XXIV. It should be observed that the persons engaged, gear and craft employed, and catch of the seed-oyster fishery are not included among the statistics of the fishery for market ovsters and other species but are shown in separate tables in this section. For a clearer understanding of the statistics published in this section, the reader is referred to the section in the latter part of this document entitled "Statistical survey procedure."

Statistics on soft clams are based on yields of 16 pounds of meat to the bushel in New York, and 20 pounds in New Jersey.
 Statistics on oysters are based on yields of 7 pounds of meat to the bushel in New York, 6.05 pounds in New Jersey, and 7 pounds in Delaware.

NOTE.—The above includes the catch made by Middle Atlantic craft in the southern trawl fishery as well as in other fisheries in the South Atlantic.

products.

Includes fresh fillets of halibut and mackerel, smoked eels, halibut, swordfish, and tuna-liver oils, menhaden products, oyster- and mussel-shell products, and miscellaneous fish meals.

Includes fresh-shucked hard clams, canned clam products and fish chowder, cod, swordfish, and tuna-liver oils, salted boned cod, pickled eels, and herring roe; and menhaden and shark products.

Includes miscellaneous fish scrap and marine-shell buttons.

Includes salted sturgeon roe, fresh-shucked oysters, oyster-shell products, king-crab scrap, and mendaden and shark products.

haden products.

NOTE.—The total value of the manufactured products for the Middle Atlantic States was as follows: By manufacturing establishments, \$18,688,605; and by fishermen, \$228,641. Some of the above products may have been manufactured from fishery products imported from another State or a foreign country; therefore they cannot be correlated directly with the catch within the State. Of the total number of persons engaged on transporting craft, 122 have been included as fishermen, and among the total number of persons engaged in the preparation of fishermen's prepared products, 285 have been included as fishermen. The whale products shown above were manufactured on floating factory ships operating in the Southern Remisphere. For additional data on the whale fishery, the reader is referred to the section in the latter part of this document entitled "Whaling."

¹ The production of this item is included under "Unclassified products."
¹ This item has been included under "Miscellaneous."
³ Includes smoked eels, haddock, finnan haddle, hake, lake trout, mackerel, scup, shad, and whiting.
⁴ Includes smoked butterfish, chubs, cisco, haddock and haddock fillets, sea herring (kippers and bloaters), lake trout, mackerel, shad, salmon, sturgeon, tullibees, and whitefish, and kippered salmon.
¹ Includes canned pickled eels, pickled sea mussels, fish paste, clam products, and turtle and terrapin

#### SEED OYSTER FISHERY: BY GRAR

Item	Dredges
OPERATING UNITS Fishermen, on vessels	Number 40
Net tonnage	89
Number. Yards at mouth.	10 12
CATCE Oysters, seed, public, spring	Bushels   Value   \$13,800

NOTE.—The seed cyster fishery of Delaware was confined to Kent County. Of the total number of persons fishing for seed cysters 13 were duplicated among those fishing for market cysters or other species. Similarly the following craft and gear were duplicated: 2 sailing vessels and 4 dredges.

#### SHAD FISHERY OF THE HUDSON RIVER

The shad fishery of the Hudson River in 1937 was prosecuted by 613 fishermen who used 299 boats, 15 haul seines, 186 drift gill nets, and 113 stake gill nets. The total commercial catch amounted to 878,190 shad, having a weight of 2,732,200 pounds and a value to the fishermen of \$212,786. This is an increase of 26 percent in the number of shad and 25 percent in their value as compared with 1936. The average price per pound received by the fishermen was about 8 cents, compared with a price of about 7 cents in 1936.

Stake gill nets accounted for 65 percent of the weight of the shad

taken, drift gill nets 34 percent, and haul seines 1 percent.

Statistics of the catch of shad in the Hudson River also are included in the catch data for New York and New Jersey which are published elsewhere in this report.

Shad fishery of the Hudson River, 1937

#### FISHERIES OF THE CHESAPEAKE BAY STATES

#### (Area XXIII) 7

The yield of the commercial fisheries of the Chesapeake Bay States (Maryland and Virginia) during 1937 amounted to 292,244,400 pounds, valued at \$6,361,234 to the fishermen, representing a decrease of 7 percent in volume and 2 percent in value as compared with the catch in the previous year. These fisheries gave employment to 16,529 fishermen, as compared with 18,283 in 1936.

This is the number given to this area by the North American Council on Fishery Investigations. It should be explained that there may be included under this area, craft whose principal fishing ports are in the area but at times fish elsewhere. Data on the operating units and catch of the fisheries of the Chesapeake Bay States have been taken largely from statistics collected by the State fishery agencies of Maryland and Virginia. Supplementary surveys, compilations, and analyses, have been made by agents of this Bureau in order that the figures may be presented in a manner comparable with those of other sections. It should be observed that the persons engaged, gear and craft employed, and the catch of the seed cyster fishery are not included among the statistics of the fishery for market cysters and other species but are shown in separate tables in this section. For a clearer understanding of the statistics pulshed in this section, the reader is referred to the section in the latter part of this document entitled "Statistical survey procedure."

There were 561 fishery wholesale and manufacturing establishments in the two States in 1937, as compared with 585 in 1936. In 1937 these establishments employed 12,005 persons, paid \$3,068,069 in salaries and wages, and produced manufactured products (canned, cured, packaged, and byproducts) valued at \$10,009,939. In 1936 the wholesale and manufacturing firms employed 12,663 persons, paid \$3,073,443 in salaries and wages, and produced manufactured products valued at \$9,813,684.

¹ Statistics on hard clams used in this table are based on yields of 8 pounds of meats per bushel for clams

1 Statistics on hard clams used in this table are based on yields of 8 pounds of meats per bushel for clams from public beds and 7 pounds for those from private beds.

2 Statistics on market oysters used in this table are based on yields of 5.98 pounds of meats per bushel in Maryland, and 6.06 pounds in Virginia.

3 The sea scallops were taken by a Virginia vessel operating off the New England and Middle Atlantic

Note.—The seed cyster fishery was prosecuted in this section only in Virginia where 1,220 fishermen using 13 motor vessels, 433 motorboats, 33 other boats, and 910 tongs took 794,100 bushels of seed cysters, valued at \$198,485 from public beds and 2,400 bushels, valued at \$600, from private beds. Of the total number of persons fishing for seed cysters, 815 are duplicated among those fishing for market cysters or other species. Similarly, the following craft and gear are duplicated: 295 motorboats, 21 other boats, and 606 tongs.

- Includes fresh fillets of sea robin; fresh pan-dressed flounders and whiting; and frozen fillets of croaker.

- Includes fresh fillets of sea robin: fresh pan-dressed thounders and whiting; and irozen miets of croaker.
  Includes alewife and blue crab dry scrap.
  Includes blue crab and miscellaneous dry scrap: menhaden, starfish and miscellaneous fish meals; and alewife and menhaden acid scrap.
  Includes canned oysters, fish paste, fish cakes, and oyster, shrimp, and terrapin soup.
  The production of this item is included under "Miscellaneous"
  Includes samoked butterfish, carp, chub, cisco, tullibees, cels, sea herring, salmon, shad, sturgeon, lake trout, and whitefish: corned alewives and tipht-pack cut alewives.
  Includes marine-shell buttons and novelties; canned cat and dog food: and alewife oil.
  Includes fresh-shucked hard clams, tight-pack alewife roe, miscellaneous fish oil, and canned blue crabs.

Note.—The total value of manufactured products in the Chesapeake Bay States was as follows: By manufacturing establishments, \$10,009,939, and by fishermen, \$14,220. Some of the above products may have been imported from another State or a foreign country; therefore, they cannot be correlated directly with the catch within the State. Of the total number of persons engaged on transporting vessels, 1,047 have been included as fishermen, and among the total number of persons engaged in the preparation of fishermen's prepared products all have been included as fishermen.

Note.—Of the total number of persons fishing for seed cysters, 815 are duplicated among those fishing for market cysters or other species. Similarly, the following craft and gear are duplicated: 295 motorboats, 21 other boats, and 606 tongs.

## SHAD AND ALEWIFE FISHERIES OF THE POTOMAC RIVER

The catch of shad in the Potomac River in 1937 amounted to 164,093 in number, 434,900 pounds in weight, and their total value to the fishermen was \$40,332. The catch of alewives for the same season amounted to 7,567,500 in number, with a total weight of 3,025,200 pounds, and a value to the fishermen of \$29,143. These figures show an increase of 21 percent in the weight and 14 percent in the value of shad as compared with 1936, and a decrease of 33 percent in weight and 21 percent in the value of alewives.

Approximately 79 percent of the shad, in weight, were taken with pound nets, and 21 percent with gill nets. More than 99 percent of the alewives were taken with pound nets, only a small quantity being taken with gill nets.

Statistics of the catch of shad and alewives in the Potomac River are also included in the catch data for Maryland and Virginia which are published elsewhere in this report.

#### TRADE IN FISHERY PRODUCTS IN WASHINGTON, D. C.

The municipal fish wharf and market in Washington, D. C., is located in the southwestern part of the city on an arm of the Potomac River. At the present time 16 firms have stalls in this market, 2 are located in the immediate vicinity of the market, 2 have stalls in the Center Market, located at Fifth and K Streets NW., and 3 are located in other parts of the city. Altogether there are 23 firms which employ 156 persons who received \$141,327 in salaries and wages during 1937. These firms conduct mainly a wholesale business although some retail trade is carried on. In 1937 manufactured products produced by firms in Washington, D. C., consisted of smoked fish and shucked oysters. The total value of these products amounted to \$10,225.

The facilities for handling fish and oysters from boats and vessels that may land at the wharf are good, but only a comparatively small quantity are brought into the city by this method. In the fall and winter considerable quantities of shell oysters are landed, but most of the oysters handled in Washington are brought in already shucked from Maryland and Virginia by trucks and other transportation facilities.

#### FISHERIES OF THE SOUTH ATLANTIC AND GULF STATES

(South Atlantic, Area XXIV; Gulf, Area XXV) 8

The yield of the commercial fisheries of the marine areas of the South Atlantic and Gulf States (North Carolina, South Carolina, Georgia, Florida, Alabama, Mississippi, Louisiana, and Texas) during 1937 amounted to 546,751,000 pounds, valued at \$14,226,370 to the fishermen, representing a decrease of 2 percent in quantity, but an increase of 5 percent in value as compared with the catch of the previous year. These fisheries provided employment for 30,244 fishermen as compared with 29,006 in 1936.

There were 725 fishery wholesale and manufacturing establishments in these States in 1937, which was 22 more than indicated by the survey in 1936. In 1937 these establishments employed 18,534 persons, paid \$3,863,777 in salaries and wages, and produced manufactured products (canned, cured, packaged, and byproducts) valued at

^{*}These are the numbers given to these areas by the North American Council on Fishery Investigations. The catch of the Mississippi River and tributaries is not included in this section. For a clearer understanding of the statistics published in this section the reader is referred to the section in the latter part of this document entitled "Statistical survey procedure."

\$15,110,653. In 1936 wholesale and manufacturing firms employed 17,095 persons, paid \$3,296,241 in salaries and wages and produced manufactured products valued at \$11,445,674.

Fisheries of the South Atlantic and Gulf States, 1937

¹ Statistics on hard crabs used in this table are based on yields of 4.07 pounds per dozen in North Carolina; 6 pounds in South Carolina; 5.71 pounds in Georgia and Alabama; 5.77 pounds in Florida; 5.74 pounds in Mississippi; 5.56 pounds in Louisiana; and 6.12 pounds in Texas.

¹ Statistics on hard clams used in this table are based on yields of 8 pounds of meats per bushel.

¹ Statistics on oysters used in this table are based on yields of 5.52 pounds of meats per bushel in North Carolina; 5.87 pounds in South Carolina; 6.21 pounds in Georgia; 5.49 pounds in Florida; 5.13 pounds in Alabama; 4.95 pounds in Mississippi; 4.09 pounds in Louisiana; and 5.64 pounds in Texas.

Note.—The catch for Mississippi includes the following products taken by Mississippi craft in Louisiana waters: Shrimp, 19,064,700 pounds, valued at \$858,027; oysters, market, spring, 8,173,000 pounds of meats, valued at \$351,784; and oysters, market, fail, 219,400 pounds of meats, valued at \$14,315. The seed oyster fishery was prosecuted in this section only in North Carolina where 17 fishermen using 8 sail boats and 14 dredges took 8,000 bushels of seed oysters, valued at \$1,760 from public beds. All of the persons and geat engaged in the seed oyster fishery are duplicated among those fishing for market oysters or other species.

I This item has been included under "Unclassified products."

- I has been included under "Uncassined products."

  A small production of oyster-ahell poultry feed manufactured in South Carolina has been included with the production of miscellaneous products in Georgia.

  This item has been included under "Miscellaneous."

- Ine production of miscelianeous products in Georgia.

  This item has been included under "Miscellaneous."

  Includes fresh fillets of king mackerel, mattonfish, snook, Spanish mackerel, and squeteagues; fresh steaks of cabio and snook; and fresh pan-dressed red drum.

  Includes smoked alewives, and saited bluefish, king whiting roe, and Spanish mackerel fillets.

  Includes saited bluefish and tenpounder, and smoked mullet.

  Includes canned hard-clam products, coquina-clam broth, and frog and turtle products.

  Includes fresh fillets of croaker, red drum, flounders, sea bass, Spanish mackerel, and squeteagues; Includes fresh fillets of croaker, red drum, flounders, sea bass, Spanish mackerel, and squeteagues; fresh pan-dressed croaker, red drum, flounders, sea bass, Spanish mackerel, scup, and squeteagues; fresh pan-dressed croaker, red drum, flounders, sea bass, Spanish mackerel, scup, and squeteagues; fresh pan-dressed croaker, red drum, flounders, sea bass, Spanish mackerel, and squeteagues; fresh pan-dressed croaker, red drum, flounders, sea bass, Spanish mackerel, and squeteagues; fresh pan-dressed ovysters; alewife scrap and oil; and shark hides, fins, and liver oil.

  Includes canned oysters and terrapin products; cooked and peeled shrimp; menhaden acid scrap and oil; and a small quantity of oyster-shell poultry feed which was produced in South Carolina.

  Includes fresh fillets of groupers, red snapper; spanish mackerel, and squeteagues; fresh steaks of groupers and red snapper; cooked and peeled shrimp; and oyster-shell poultry feed and lime.

  Includes canned soft crabs, crab and shrimp gumbo, terrapin products, turtle meat, fish bouillon, crawfish soup, and frog products; and oyster-shell poultry feed and lime.

  Notz The total value of manufactured products in the South Atlantic and Gulf States was as follows:

Note.—The total value of manufactured products in the South Atlantic and Gulf States was as follows: By manufacturing establishments, \$15,110,658; and by fishermen, \$240,902. Some of the above products may have been imported from another State or a foreign country; therefore, they cannot be correlated directly with the catch within the State. All except 13 of the persons engaged in the preparation of fishermen's manufactured products have also been included as fishermen, and 312 of the persons shown on transporting craft have also been included as fishermen. This should be considered when computing the total number of persons in the fishery industries exclusive of duplication.

## SPONGES SOLD AT THE EXCHANGE, TARPON SPRINGS, FLA.

During 1937 sponges sold on the exchange at Tarpon Springs, Fla., amounted to 561,943 pounds, valued at \$1,097,301. This is a decrease of 11 percent in quantity but an increase of 6 percent in value as compared with the transactions on the exchange in 1936. Revised data on the volume of sponges sold on the exchange in 1936 show

that sales during that year totaled 628,226 pounds, valued at \$1,035,429. Of the total sponges sold on the exchange during 1937, 43,218 pounds, valued at \$163,745, were large wool; 26,511 pounds, valued at \$60,923, were medium and small wool; 329,018 pounds, valued at \$752,032, were wool rags; 130,562 pounds, valued at \$96,536, were yellow; 16,954 pounds, valued at \$11,807, were grass; and 15,680 pounds, valued at \$12,258, were wire. It is estimated that sponges valued at \$1,250 were sold outside the exchange.

#### FISHERIES OF THE PACIFIC COAST STATES

The yield of the commercial fisheries of the Pacific Coast States (Washington, Oregon, and California) during 1937 amounted to 1,576,877,400 pounds, valued at \$28,776,385 to the fishermen, representing a decrease of 18 percent in volume, but an increase of 16 percent in value as compared with the catch in the previous year. These fisheries gave employment to 21,555 fishermen as compared with 20,620 in 1936.

There were 330 fishery wholesale and manufacturing establishments in the three States in 1937, as compared with 339 in 1936. During 1937 these establishments employed 19,792 persons, paid \$10,669,409 in salaries and wages, and produced manufactured products (canned, cured, packaged, and byproducts) valued at \$56,149,695. In 1936 the wholesale and manufacturing firms employed 16,589 persons, paid \$9,365,375 in salaries and wages, and produced manufactured products valued at \$52,498,170.

^{*}Data on the operating units and catch of the fisheries of the Pacific Coast States have been taken largely from statistics collected by the various State agencies. Supplementary surveys, compilations, and analyses have been made by agents of this Bureau in order that the figures may be presented in a manner comparable with those of other sections. While statistics of the fisheries of California are for the calendar year, those for Oregon and Washington are for the fiscal year ending March 31, 1938, except that statistics of the halibut fishery in these latter States are for the calendar year. For a clearer understanding of the statistics published in this section the reader is referred to the section in the latter part of this document entitled "Statistical survey procedure."

Note.—In addition to the California operating units shown above, 47 motor vessels, 43 accessory boats, and 7 motorboats having their home ports in the State of Washington, and 19 motor vessels, 19 accessory boats, and 21 motorboats having their home ports in the State of Oregon, were operated off California and contributed to the California catch. The following gear was operated by these craft: 46 sardine purse seines, 1 tuna purse seine, 3 sardine ring nets, 6 set and hand lines, and 282 troll lines.

Includes the catch taken off Latin America.

All of the cod reported for California and most of the Washington catch were taken off Alaska.

¹ The production of this item has been included under "Unclassified products."

¹ This item is usually an intermediate product, and although included in the total, may be shown in its final stage of processing in this or another State.

¹ Includes the production of both edible and industrial salmon oils.

¹ Includes fresh fillets of rockfishes; frozen fillets of halibut and "lingcod"; and fresh-shucked bay scallops.

¹ Includes fresh fillets of flounders, "lingcod", and rockfishes; frozen fillets of flounders, "lingcod", and salmon; frozen salmon steaks; and fresh-shucked hard clams.

¹ The production of this item has been included under "miscellaneous."

¹ Includes green salted cod in process partly boned, spiced berring, and salmon belies.

Includes green salted cod in process, partly boned, spiced herring, and salmon bellies.
Includes salted barracuda, black sea bass, white sea bass, bonito, mackerel, pilchards, and yellowtail; pickled and spiced herring; green salted cod in process, partly boned; and boneless and absolutely boneless

Salted cod.
Includes smoked chubs, herring, mackerel, and miscellaneous fish.
Includes canned salted cod, shad roe, albacore tuna, fish paste, and hard clam chowder.
Includes canned salmon eggs for bait, kippered sturgeon, albacore tuna, whole razor clams, razor clam. 11 Includes canned salmon eggs for oatt, appered sturgeon, absolute talls, whole talls, talls, juice, and Japanese oysters.
12 Includes salmon, salmon egg, grayfish, and miscellaneous fish meals.
13 Includes shark and miscellaneous fish meals, and miscellaneous green scrap.
14 Includes salmon, grayfish, and miscellaneous fish oils; and halibut, "lingcod," sablefish, and tuna

liver oils.

116 Includes shark and whale oil; and shark and miscellaneous fish liver oils.

15 Includes smoked herring bloaters, and kippered herring; kelp products; and clam-shell lime.

15 Includes salted sablefish; smoked shad and sturgeon, and kippered salmon; salmon and salmon egg
meals; oyster-shell poultry feed and lime; and marine-shell novelties.

15 Includes fresh-shucked, eastern, Japanese, and native oysters; fresh-cooked shrimp meat; sun-dried

5 hrimp; canned tuna roe and squid; liquid glue; kelp products; and marine-shell novelties.

Note.—The total value of manufactured products in the Pacific Coast States was as follows: By manu-NOTE.—The total value of manufactured products in the racine coast clauses was as ionows: by manufacturing establishments, \$56,148,285; and by fishermen, \$213,561. Some of the above products may have been imported from another State or foreign country; therefore, they cannot be correlated directly with the catch within the State. All of the persons engaged in the preparation of fishermen's manufactured products in the preparation of fishermen's manufactured products. ucts have also been included as fishermen.

* Caught almost entirely for she unification of such that the state of the State in number discarded.

* Statistics on the catch of salmon except those taken by troll lines, are reported to the State in number rather than pounds. The factors used in the above table for converting number of salmon to weight in pounds were as follows: Blueback, red, or seekeye, 7 pounds; chimook, or king, 19.77 pounds; chum or keta, 10 pounds; humpback, or pink, 5 pounds; and silver, or coho, 7.97 pounds.

* The weight of crabs shown is based on an average of 20 pounds per dozen.

* Statistics on hard clams are based on yields of 28 percent edible meats for butter clams and 24 percent for little-neck clams.

* Statistics on oysters are based on yields of 18 percent edible meats for native oysters and 10 percent for Japanese cysters.

10 The weight of bay scallops is based on a yield of 17 percent edible meat.

Includes the catch of smelt by bag drag nets, shown separately prior to 1935.

Fished only on Indian reservations.

In addition, the vessels of the Pacific coast halibut fleet landed approximately 590,000 pounds of halibut, sablefish, and "lingcod" livers at Seattle, valued at \$277,400.

Most of these cod were taken off Alaska.

Caught almost entirely for the utilization of the livers for grayfish oil. Most of the fish carcasses were

i Fished by Indians on their reservations.

1 Statistics on the catch of salmon except those taken by troll lines are reported to the State in number rather than pounds. The factors used in the above table for converting number of salmon to weight in pounds were as follows: Blueback, red, or sockeye, 5 pounds; chinook or king, 20.78 pounds; chum or keta, 11.09 pounds; silver or coho, 10 pounds; and steelhead trout, 9 pounds.

2 Steelhead trout shown in this table were taken on Indian reservations.

4 The weight of crabs shown is based on an average of 22 pounds per dozen.

2 The weight of razor clams shown is in pounds of edible meats, based on a yield of 42 percent of the round walsht.

weight.

The statistics on cysters used in this table are based on a yield of 12 percent of edible meats for Japanese and native cysters and 13 percent for eastern cysters.

¹ Of the species listed the following are taken off the Oregon and Washington coasts but landed in the Columbia River district: "Sole", halibut, "lingcod", rockfishes, sablefish, and tuna. Most of the troll-caught salmon were also taken in coastal waters.

The catch by paranzella nots was made by fishermen from California.

The Oregon coast pilchard fishery was prosecuted almost entirely by Washington and California purse-seine vessels. See separate sections for data on operating units in the fishery.
 The weight of razor clams is that of edible meats, based on a yield of 42 percent of the round weight.
 Mixed clams consist principally of eastern soft-shell clams. The weight shown in that of edible meats, based on a yield of 21 percent of the round weight.

#### HALIBUT FISHERY OF THE PACIFIC COAST 10

The halibut fishery of the Pacific coast, which is prosecuted by United States (including Alaska) and Canadian vessels, ranks as one of the foremost fisheries of that section. During 1937 the total catch of halibut by vessels of both nationalities amounted to 48,659,000 pounds, valued at \$3,828,000. This is an increase of 1 percent in volume and 6 percent in value, as compared with the catch and its value in 1936. Of the total catch in 1937, 76 percent was taken by United States craft and 24 percent by Canadian craft. Considered according to ports of landing, 43 percent was landed at Seattle, Wash.; 39 percent at Canadian ports; and 18 percent at ports in Alsaka.

Halibut fishery of the Pacific coast, 1937

UNITED STATES OPERATING UNITS: BY FLEET CLASSIFICATION

Item	Washing- ton fleet	Alaska fleet	Total
Regular halibut vessels:	Number	Number	Number

#### VESSEL FISHERIES AT SEATTLE, WASH.

A total of 52,320,295 pounds of fishery products, valued at \$3,664,057, were handled by Seattle wholesale dealers during 1937, exclusive of quantities received by transporting vessels or by rail from Alaska or Canada. This represents an increase of 5 percent in volume and 13 percent in value as compared with the quantity and value of the products handled during the preceding year. Of the total quantity handled, 25,306,450 pounds, valued at \$2,130,431, were landed by fishing vessels—a decrease of 6 percent in volume and 3 percent in value as compared with the previous year. Receipts by wholesale dealers from sources other than Alaska or Canada, or from vessels in the halibut fleet, amounted to 27,013,845 pounds, valued at \$1,533,626, which is an increase of 19 percent in volume and 46 percent in value.

Note.—In addition to the above, it is estimated that about 1,190,477 pounds of halibut, sablefish, "ling-cod," and rockfish livers, valued at approximately \$561,856, were landed by the combined fleets at Pacific coast ports during 1936.

The tabulation does not include landings at ports south of Seattle, Wash., which are normally less than 4 percent of the annual Pacific coast catch.

¹ This tabulation does not include fish received from Alaska or Canada or vessels in the halibut fleet.

^{178,550} dozen.

NOTE.—The yields of bivalve mollusks have been converted from weights in the shell to weights of meats on the following basis: Hard clams, 25 per cent, and bay scallops 17 percent.

#### LAKE FISHERIES 11

In 1937 the yield of the fisheries of the Great Lakes, including those of the international lakes of northern Minnesota, in the United States and Canada amounted to 116,063,700 pounds, representing a decrease of 7 percent as compared with the catch in the preceding year.

Considering the fishery of United States craft only, the catch amounted to 83,958,400 pounds, valued at \$6,033,084, which is a decrease of 11 percent in volume and 6 percent in value as compared with the catch in the previous year. These fisheries gave employment to 6,418 fishermen as compared with 5,623 in the previous year.

Where there has been a Canadian catch of these species it is included under "Miscellaneous."

¹¹ The statistics of the catch presented herewith were obtained principally from records of the various State fishery agencies. The data for the operating units (fishermen, vessels, boats, and gear) of the United States were obtained largely by Bureau agents in a special canvass; although State records in several instances were very helpful in this work. In all cases the statistics collected are for the calendar year, except for Lake of the Woods, Rainy Lake, and Lake Namakan in Minnesota, which are for two seasons. For Lake of the Woods, the seasons are from June 1 to November 1 and December 1 to April 1 and for Rainy and Namakan Lakes from May 15 to November 1 and December 1 to April 1. The catches for these two seasons, in the order named, have been combined to constitute a year. The quantity of fish taken in these lakes between January 1 and April 1 is estimated at less than 3 percent of the total catch.

10 Includes fresh fillets of lake trout and white bass; frozen fillets of lake trout; and spiced sea herring.
11 Includes smoked carp and spiced alewives.
12 Includes smoked lake trout and whitefish.
13 Includes fresh fillets of carp, halibut, lake herring, lake trout, pickerel, salmon, red snapper, and suckers, and canned soft clam chowder.
14 Includes fresh fillets of blue pike, lake herring, and yellow perch; frozen fillets of sauger pike; and smoked butterfish, carp, mackerel, and sablefish.
14 Includes fresh iske trout fillets; spiced chub and alewives; burbot-liver oil; poultry feed and lime from fresh-water mussel shells, and canned whitefish caviar.
14 Includes smoked lake trout, salmon and whitefish; and burbot-liver oil.

Note.—The total value of the manufactured products for the Lake States was as follows: By manufacturing establishments, \$3,196,461; and by fishermen, \$51,546. Some of the above products may have been manufactured from products imported from another State or a foreign country: therefore, they cannot be correlated directly with the catch within the State. All of the persons engaged in the preparation of fishermen's manufactured products have also been included as fishermen and 12 of the persons shown on transporting craft have also been included as fishermen. This should be considered when computing the total number of persons in the fishery industries exclusive of duplication.

#### FISHERIES OF THE MISSISSIPPI RIVER AND TRIBUTARIES 12

The most recent complete catch statistics of the fisheries for the States of the Mississippi River and tributaries are those collected for the year 1931. The yield of fishery products in that year amounted to 82,382,523 pounds, valued at \$2,897,357, which was a decrease of 22 percent in quantity and 36 percent in value as compared with the quantity and value of the catch in 1922, the year for which the most recent preceding survey was made. Detailed statistics of the fisheries of the Mississippi River and tributaries for 1931 appear in "Fishery Industries of the United States, 1932" by R. H. Fiedler, Appendix III to the Report of the Commissioner of Fisheries for the fiscal year 1933. A summary of these fisheries in 1931, as well as certain data for 1937, appear in the following tables:

¹ The production of this item is included under unclassified products.

<sup>Pata are for 1937.
Includes mussel-shell chips and novelties.
Includes smoked buffalofish and tullibees.
Includes smoked eels, salmon, and sturgeon.
Includes smoked buffalofish, butterfish, carp, lake trout, paddlefish, sablefish, salmon, tullibees, and</sup> whitefish.

Note.—Unless otherwise indicated the data are for 1931. The total value of the manufactured products for the States of the Mississippi River and tributaries was as follows: By manufacturing establishments \$4,055,358; and by fishermen \$8,751. Some of the products may have been manufactured from fishery products imported from another State or a foreign country, therefore, they cannot be correlated directly with the catch within the State.

#### FISHERIES OF ALASKA 18

The commercial catch of fishery products in Alaska during 1937, exclusive of whales, amounted to 825,783,422 pounds, valued at \$14,237,771, which is a decrease of 11 percent in quantity but an increase of 2 percent in value as compared with the catch in 1936. Of the total catch in 1937, 593,383,891 pounds, valued at \$11,876,351, consisted of salmon; 229,340,640 pounds, valued at \$2,142,306, other fish; and 3,058,891 pounds, valued at \$219,114, shellfish. In addition, 376 whales were taken. These fisheries gave employment to 11,570 fishermen, 2,159 persons on transporting craft, and 16,602 persons in fishery wholesale and manufacturing industries—a total of 30,331 persons, which is a decrease of less than one half of one percent as compared with the number employed in 1936.

[&]quot;Statistics for the fisheries of Alaska are collected and compiled by the Alaska Division of this Bureau. A summary of these statistics appears in this section. For detailed figures the reader is referred to "Alaska Fishery and Fur Seal Industries," by Ward T. Bower, Appendix II to the report of the Commissioner of Fisheries for the fiscal year 1938.

Note.—The output of fresh and frozen halibut includes all fares of the Alaska fleet, some of which were landed at other than Alaska ports. The amount of livers landed by the Alaska fleet has not been reported, and the quantity shown herein is the estimated amount landed in Alaska. The total landings of halibut, other than livers, in Alaska in 1937 mounted to 8,705,204 pounds, valued at \$557,911 (including 3,000 pounds, valued at \$190, landed by Canadian vessels).

### WHALING 14

The history of whaling presents one of the most romantic chapters in the annals of seafaring life. Since its inception, in the Bay of Biscay early in the twelfth century, whaling has been carried on at one time or another in all the oceans of the world.

At the beginning of the eighteenth century the New England colonists became prominent in the industry, and by 1846 there were 735

American vessels engaged in the fishery.

The American fishery continued to expand and flourish until the discovery of petroleum in the United States about 1850. Due to lower production costs, the distillation products of petroleum quickly replaced whale oil for illumination purposes. In 1871 practically the entire Arctic fleet was destroyed by ice. This catastrophe, followed by the substitution of steel for whalebone, marked the end of

American supremacy.

The relentless, unrestricted pursuit of these huge marine mammals led inevitably to the virtual extermination of certain species in first one sea and then another. In 1887 new impetus was given the stricken industry by the invention of the harpoon gun by a Norwegian sailor, Svend Foyne. The harpoon gun, shooting a heavy harpoon with an exploding bomb, and mounted on the bow of fast boats of 100 to 150 tons, made it possible to capture the large finback, blue, sei, and humpback whales, which previously had been too speedy and dangerous to hunt. A few years later a violent controversy, which culminated in a successful protest by the Norwegian cod fishery, closed Norwegian waters to whaling (Norwegian Fisheries Act of Jan. 7, 1904). This led to the exploitation of distant fields, the establishment of new shore stations, and ultimately to the introduction of the huge modern factory ship. With the advent of the factory ship the Antarctic, hitherto unexplored, was invaded.

Shortly after the beginning of the twentieth century, oil chemists learned the manner of converting whale oil into hardened fat. Later, the World War created a demand for gylcerine and once more whale oil

returned as an important product of commerce.

By 1930 Antarctic whaling had developed to such amazing proportions that for the first time leaders in the industry were forced to heed the warnings of eminent biologists and conservationists who had long followed with misgivings this unremitting warfare against these creatures. In 1931 the League of Nations provided for a committee of experts to consider the question. This committee adopted a Convention for the Regulation of Whaling. The Convention was signed by 26 nations, including the United States. In the United States, the Whaling Treaty Act of May 1, 1936, and the Joint Regulations of the Secretary of the Treasury and the Secretary of Commerce, of October 9, 1936, promulgated thereunder, gave effect to this Convention

An International Whaling Conference, held in London, England, on June 8, 1937, drafted an Agreement to supplement and extend the International Convention for the Regulation of Whaling. This agreement was ratified by the United States and the new Joint

¹⁴ This section was prepared by Ralph A. Ferrandini, Special Whaling Agent, Law Enforcement Division.

Regulations of the Secretary of the Treasury and the Secretary of

Commerce were signed by the President December 20, 1938.

The original Convention and subsequent legislation, among other things, prohibited the killing of right and gray whales; set definite limits on various other species, required the licensing of all shore stations, factory ships, and killer boats, and the collection of statistical and biological data on all whales killed.

In general it may be stated that there are virtually two groups of whales. All have their young in the tropical waters; then, accompanied by their calves, one group migrates to the Antarctic and the other to the Arctic. The Northern group leaves the tropical waters of the Caribbean Sea and Lower California in the spring or early summer, travels to the Arctic Seas, and returns along the same general route in the fall. Thus, whaling in Northern waters usually starts in May or June and ends in October.

The seasons are reversed in the Southern Hemisphere; therefore, the Southern group leaves the tropical waters off the coasts of Africa, South America, and Australia in the Antarctic spring, i. e., October, migrates to the Antarctic polar seas during the Antarctic summer and returns to tropical waters in autumn (March and April). Whaling in the Antarctic is restricted to a definite season. The season opens December 8 and closes March 7. During 1937-38 the season

was extended to March 15.

The American whaling industries operated for the first time under these new regulations during the 1937-38 season. The value of the whale products are conservatively estimated at \$6,000,000, and fees for whaling licenses yielded \$10,250 to the Federal Government.

A Coast Guard inspector was assigned to each shore station and factory ship. Uniform methods for the collection of statistical and biological data were inaugurated by the Bureau of Fisheries. Samples of stomach contents were taken when practicable and a comprehensive report containing the results of the analyses of stomach contents, as well as detailed information concerning all American whaling operations, was prepared by the Bureau and forwarded through the State Department to the International Bureau for Whaling Statistics, Oslo. Norway.

The following tables show the extent of American participation in whaling during the 1937-38 season, as well as the total production of

whale products by areas:

### STATISTICAL SURVEY PROCEDURE

In order that those who use the statistical data contained in this and previous reports of the Division of Fishery Industries may be informed as to the source of the figures and methods for their collection, it has been deemed advisable to outline, in considerable detail, the statistical survey procedure followed by the Division. This procedure has been developed over a period of years, and changes in method have been made at times where such changes have appeared to work toward general improvement. While the surveys in the several sections are not made in the same manner, owing to varying facilities and records in different States, an attempt has been made to make the data collected by various methods in the producing areas comparable with respect to the same year as well as over a period of years. Throughout the entire plan it has been the intention to coordinate State and Federal fishery statistical work so that there will be as little duplication of effort as possible. The procedure will be discussed under two main heads-"Sectional surveys" and "Local and special surveys."

#### SECTIONAL SURVEYS

Statistical surveys of the fisheries and fishery industries of the various sections of the United States occupy by far the greatest part of the time of the statistical personnel of the Division. It is in the course of these surveys that the statistical and marketing agents visit the individual fishing localities of the various States to collect statistics of the volume of the catch of fish and its value, employment in fishing, quantity of fishing gear, number and classification of fishing and transporting craft, employment in wholesale and manufacturing establishments, and the volume and value of manufactured fishery products and byproducts. The various phases of these surveys are discussed in detail in the sections following.

History.—The first comprehensive statistical survey of the fisheries and fishery industries of the United States was made for the year 1880 by George Brown Goode, Assistant Director of the U.S. National Museum, and associates, with the cooperation of the Commissioner of Fisheries and the Superintendent of the Tenth Census. Data for specific fisheries, or restricted sections for years prior to 1880, were also collected in this early survey and recorded in Mr. Goode's reports. The survey for 1880, however, did not include the Mississippi River and tributaries. Periodic general surveys of a limited number of States or limited areas of the United States were made for various of the intervening years between 1880 and 1908 In 1908 a survey of the entire United States and from 1909 to 1928. The next general survey of the entire United States was not made until 1931, although complete data for all sections, excluding the Mississippi River and tributaries, were collected for 1929 and 1930. Complete data on the catch and operating units for all sections. excluding the Mississippi River and its tributaries, were collected for In the latter survey, however, lack of sufficient funds prohibited collection of data on wholesale and manufacturing firms except those data collected as a part of the canned fishery products and bvproducts surveys. Complete general canvasses were made of the Chesapeake and Pacific States for the years from 1933 to 1937, inclusive, the New England and Middle Atlantic States for 1933, 1935, and 1937, and the South Atlantic, Gulf, and Lake States for 1934, 1936, and 1937. Complete data on the catch of the fisheries of the Lake States were also collected for 1933 and 1935.

Following is a summary indicating the years for which statistics were collected on the fisheries and fishery industries in the various sections. Figures for the more recent years are available for free distribution from the Bureau in bulletin form, but figures for the earlier years are available only in the various printed reports of the Bureau. These reports are available for reference in the Bureau's

library and at many public libraries.

In the New England States statistics on the catch of the marine fisheries, and those conducted in the coastal rivers and bays of these States, were collected for the years 1880, 1887, 1888, 1889, 1898, 1902, 1905, 1908, 1919, 1924, 1928, 1929, 1930, 1931, 1932, 1933, 1935, and 1937. For most of these years data on operating units and wholesale and manufacturing trade also were collected. In addition to the above, a partial statistical survey was made for the entire section in 1892; a partial survey of the fisheries in Maine, New Hampshire, and Massachusetts for the fiscal year 1897; the lobster fishery for 1900 and 1913; the oyster fishery for 1910; the shad and alewife fisheries for 1896; the menhaden industry for 1912; the fisheries of Massachusetts for 1879; and the fisheries of Connecticut for 1925 and 1926.

Statistics on the catch of the marine fisheries and those conducted in the coastal rivers and bays of the Middle Atlantic States were collected for the years 1880, 1887, 1888, 1889, 1890, 1891, 1897, 1898, 1901, 1904, 1908, 1921, 1926, 1929, 1930, 1931, 1932, 1933, 1935, and 1937. Data on operating units and wholesale and manufacturing trade also were collected for most of these years. In addition to these a statistical survey was made of the coastal fisheries of these States in 1915; catch in all States except New York, in 1892; the shad and alewife fisheries in 1896; the shad fisheries of the Delaware River in

1910; the shad fisheries of the Chesapeake Bay and tributaries in 1909; the menhaden industry in 1912; the lobster fisheries in 1900 and 1913; and the oyster fishery in 1911. The years for which statistics are available on the shad fishery of the Hudson River are given in the section entitled "Shad and alewife fisheries."

In the Chesapeake Bay States statistics on the catch of the marine fisheries and those conducted in coastal rivers and bays of these States were collected for the years 1880, 1887, 1888, 1890, 1891, 1897, 1901, 1904, 1908, 1920, 1925, and for all the years from 1929 to 1937, inclusive. Data on operating units and wholesale and manufacturing trade also were collected for most of these years. In addition to the above, a statistical survey was made of the crab fishery for 1915; the oyster fishery and menhaden industry for 1912; and the shad and alewife fisheries for 1896, 1909, and 1915. The years for which statistics of the shad and alewife fisheries of the Potomac River are available are given in the section entitled "Shad and alewife fisheries."

In the South Atlantic and Gulf States statistics on the catch of the marine fisheries and those conducted in the coastal rivers and bays of these States were collected for the years 1880, 1888, 1889, 1890, 1897, 1902, 1908, 1918, 1923, 1927, 1928, 1929, 1930, 1931, 1932, 1934, 1936, and 1937. Data on operating units and wholesale and manufacturing trade also were collected for most of these years. In addition to the above, a statistical survey was made of the fisheries of these States, excluding Florida and Alabama, for 1887; the shad fishery of the South Atlantic States for 1910; the shad and alewife fisheries of the South Atlantic States for 1896; the sturgeon fishery of Florida for 1900; the menhaden industry of the South Atlantic States for 1912; the shrimp fishery for 1916; the oyster fishery of the South Atlantic States for 1910; and the oyster fishery of the Gulf States for 1911.

In the Pacific Coast States statistics on the catch of the marine fisheries and those conducted in the coastal rivers and bays of these States were collected for the years 1880, 1888, 1892, 1895, 1899, 1904, 1908, 1915, and for all the years from 1922 to 1937, inclusive. These surveys have usually included data on operating units and wholesale and manufacturing trade. In addition to the above, statistics were obtained on the fisheries of California from 1918 to 1921, inclusive, and for the oyster fishery in 1912.

Statistics on the catch of the fisheries of the Great Lakes were collected for the years 1880, 1885, 1890, 1893, 1899, 1903, 1908, and for all the years from 1913 to 1937, inclusive. Statistics of the operating units and of the wholesale and manufacturing trade were collected for most of the years when canvasses were made from 1880 to 1908, and in 1917 and 1922 as well as in most of the years from 1926 to 1937, inclusive. In addition to the above a survey was made of the fisheries of Lake Ontario and of certain fisheries in other lakes for the year 1897.

Statistics of the catch of the fisheries of the Mississippi River and its tributaries were collected for the years 1894, 1899, 1903, 1908, 1922, and 1931. In addition, figures have been obtained of the fisheries of Lakes Pepin and Keokuk for the years 1914 and 1917 and the years from 1927 to 1937, inclusive, and of the fisheries of the Mississippi River between Lakes Pepin and Keokuk for the years 1929 to 1937, inclusive.

Statistics also were collected on the fisheries of certain interior waters, other than the fisheries of the Great Lakes and the Mississippi

River and its tributaries, for the years 1894, 1895, 1900, and 1902. Statistical agents.—The statistics contained in this volume have been collected by a corps of trained statistical and marketing agents which comprises a part of the permanent staff of the Division of Fishery Industries of the Bureau. In the main they are college graduates and were recruited through civil-service examination. college, many of the men pursued biological or technical courses, largely in fishery work, which has especially suited them for coping with the many biological and technical aspects encountered in canvassing the fisheries. This training has been especially helpful in identification of the species which, because of the many local names

applied to a particular species, causes considerable confusion.

Period covered .- In conducting the fishery statistical surveys, agents are dispatched to the districts to be surveyed as early in the calendar year as they can be spared from the tabulation and preparation for publication of their previous season's work. They collect statistics of fishery operations for the year preceding that in which they are working; and, since their field work occupies the greater part of the year, it is usually at least a year from the end of the calendar year for which they are collecting data until the figures are published. Most of the figures are collected for the calendar year. Where there are variations from this general practice, explanatory notes appear in the tables. Prior to 1930, statistics on the catch of oysters in the Atlantic and Gulf States were collected for the oyster season; that is, from September to Beginning with 1930 and down to the present, they April, inclusive. have been collected on the basis of the calendar year.

Scope.—The scope of the coastal statistical surveys includes canvasses of the commercial fisheries of the oceans and bays and of the coastal rivers as far inland as commercial fishing is important. usually coincides with the range of commercial fishing for anadromous Statistics of the fisheries of the Mississippi River cover canvasses of the fisheries of the Mississippi River proper as well as all of its tributaries wherein commercial fishing for either fish, crustaceans, or mollusks is prosecuted. Statistics of the fisheries of the Great Lakes cover canvasses of the fisheries prosecuted in the Lakes proper, adjacent bays, and the international lakes of northern Minnesota, as well as rivers which sustain a commercial fishery having outlets into these waters. Surveys for statistics of the wholesale and manufacturing fishery industries cover such plants located in the coastal, river, and lake areas adjacent to the waters mentioned above.

Methods of collection.—Several methods for the collection of fishery statistics are employed, each of which has been carefully studied to obtain the best results with the available personnel and funds. most instances the agents obtain lists of the names of fishing vessels, names or numbers of motorboats, and names of owners of these craft from local customs officials. Also it often is possible to obtain the names of licensed commercial fishermen and occasionally some statistics on the catch from several of the State fishery agencies; from other

State, county, or city agencies; or from private organizations. With such preliminary records as are available for their guidance the

agents then visit each fishing community in their field unless their preliminary records are so complete that personal visits in some areas may be eliminated. While it is impossible for the few agents available for this work to interview each fisherman in a given locality, the more important ones are visited, and a sufficient number of those of lesser importance are interviewed to obtain reliable information on their production. In practice virtually all wholesale firms are visited, as well as captains of fishing vessels (those of 5 net tons or over), and

also most of the more important inshore fishermen.

In the Great Lakes and Pacific Coast States such exceptional cooperation has been obtained in recent years from the State fishery agencies in the collection of statistics that only fragmentary surveys need be made by the Bureau's agents to obtain the necessary data. Also the State fishery agencies in Maryland and Virginia recently have developed very complete statistical systems which greatly facilitate the Bureau's canvasses in these States.

As regards the fisheries of the Great Lakes and international lakes of northern Minnesota, the Bureau obtains most of the catch statistics and usually the value of the catch direct from the records of the State fishery agency. To obtain data on the number of fishermen, boats, vessels, and gear, the Bureau conducts such personal surveys among the fishermen as may be necessary to supplement the State

records.

Bureau agents are stationed at Seattle, Wash., and Terminal Island, Calif., who survey the fisheries of the Pacific Coast States. As a rule they obtain figures on the volume of the catch from the records of the several State fishery agencies. In most cases the value of the catch is derived from dealers' records and sometimes from estimates of prices. In Washington and Oregon the offshore fisheries are surveyed separately by the Bureau's agent to obtain data on the number of operating units, catch, and value of the catch. Statistics of the wholesale fishery industry for this section are obtained largely by personal interviews of the agents.

In the administration of the Alaska fisheries the Bureau obtains sworn statements concerning their activities from those prosecuting These statements are compiled by the the fisheries in this area.

Alaska Division of this Bureau.

Statistics of the volume of the catch of fish of the Pacific Coast and Great Lakes States are usually shown in weights as landed, which may be in the round or dressed condition. Statistics on the volume of the catch of fish taken in the remainder of the United States are shown in round weight.

The figures in the tables for shellfish represent the weight of the meats in the case of univalve and bivalve mollusks and gastropods, and the round weight of crustaceans and such mollusks as squid and

octopus.

Shore and vessel fisheries.—In general, statistics of the shore fisheries, as collected by the agents, include data on the number of casual and regular fishermen; number of motor and other fishing boats and accessory boats; kind and quantity of gear used, and the volume, value, and method of capture of each species caught by boats (for our purpose craft of less than 5 net tons capacity are called "boats") for each locality or group of localities. This method is not followed in some sections where the availability of data collected by the State fishery agencies obviates the necessity of detailed locality surveys.

Statistics of the vessel fisheries include data on the number of the crew, rig of vessels, net tonnage, kind and quantity of gear used, accessory boats carried, and volume, value, and method of capture of each species caught by each vessel (for our purpose craft of 5 net tons' capacity or more are called "vessels"). As in the shore fisheries, the availability of figures collected by State fishery agencies may eliminate the necessity of our agents collecting these data for each vessel.

Statistics on the quantity of gear operated indicate the maximum number of units fished at any one time during the year. Gear carried

in reserve for replacement is not enumerated.

All persons engaged in commercial fishing operations are included as fishermen. For our purpose these have been divided into "regular" and "casual" fishermen. Regular fishermen are those who receive more than one-half of their annual income from fishing; and casual fishermen are those whose principal business is something other than fishing, and who receive less than one-half of their annual compensation from fishing.

The catch of fish is credited to the principal port of arrival and departure of the craft rather than its point of ownership, registration, documentation, or its port of landing. This accounts for catches of fish being shown in areas where they are not common, since fishing vessels frequently fish in areas far from their principal fishing port.

Wholesale and manufacturing trade.—All persons or firms engaged in the wholesale buying and selling of fishery products or who produce manufactured fishery products are surveyed under this title. Where the business of fishing and wholesaling or manufacturing is combined, that part of the business devoted to either of the latter two phases is included in the wholesale and manufacturing survey and the part devoted to fishing is included in the shore or vessel fisheries. wholesale business is conducted with no manufacturing and the business is so small that the full time of one man over the whole year or season is not required, it is then disregarded as a wholesale business. If commodities other than fishery products are handled, the persons engaged, and salaries and wages paid, are prorated; and only that part concerned with fishery products is included. If such a firm required less than the full time of one man over the whole year or season and if it does not manufacture, it is not included in the can-Retail firms that manufacture or whose wholesale business exceeds the retail part are included. Persons or firms engaged in the motortrucking of fishery products are included as wholesalers if they are engaged in wholesale buying and selling.

Buyers for a central firm are not canvassed as wholesale dealers unless they ship direct to the firm's customers from the buying point.

Fishermen or fishing concerns, except manufacturers, who do not buy fishery products are not included under this heading except that oyster-shucking firms are included provided shuckers are employed, and irrespective of whether all or part of the oysters used are taken from the firms' privately owned beds.

Manufacturing concerns include those which prepare packaged fishery products; salted, spiced, smoked, dried, or otherwise cured fishery products; canned fishery products; or fishery byproducts.

Fishermen who manufacture are surveyed to obtain the number of persons so employed and the volume and value of the products prepared.

In collecting statistics of manufacturing firms, the agents obtain data on the production for each plant in producing areas of products

as marketed by the plant. Such products are usually "final" and in form for consumption; however, the products may be "intermediate" and require further processing before reaching the consumer markets. An outstanding example of an intermediate product is green-salted groundfish, which almost invariably is further processed before final marketing. In reviewing the statistics of manufactured products it should be observed that intermediate products are not shown where they are prepared to the final stage in the original plant. An exception to this rule, however, is in the case of the production of mild-cured salmon, which, on account of its importance, is shown in its entirety, whether further processed in the producing plant or not. In this connection it should also be stated that several of the byproducts for which statistics are shown may be intermediate, and the plants producing the final products are not surveyed by this Bureau. Outstanding among such products are marine-animal oils, scrap, and meal.

Statistics of persons engaged in wholesale and manufacturing establishments are reported in three groups: Proprietors, salaried

employees, and wage earners.

Proprietors represent those persons who devote their time to the conduct of the enterprise and receive their compensation in the form of profits. Managers of branch houses are not classified as pro-

prietors.

Salaried employees usually include those persons paid by the week or month, while wage earners usually consist of those paid on a per diem or piece-work basis. This, however, is not true in all cases, since the distinction between these two classes depends primarily on the character of the work done rather than the unit of time employed for calculating rates of pay. In general, office employees are classified as salaried employees. Other employees, including plant workmen, are classed as wage earners. Plant foremen or superintendents are classified as salaried employees unless they are principally engaged in manual labor; in which case they are classified as wage earners. Active officers of corporations are classified as salaried employees. Statistics of wage earners are shown in two forms: The average number employed during the operating season; and the average number employed during the year (the monthly average for the year).

Transporting trade.—Statistics are obtained on the number of the crew and number of boats and vessels engaged in transporting fishery products from the fishing grounds to port or from port to port. However, if a craft is engaged in catching fish at any time of the year it

is included as a fishing craft rather than as a transporter.

Publication of data.—Statistics of employment in the fisheries, craft and gear engaged, catch and value of catch, and certain data on industries related to the fisheries are summarized and published in bulletin form as soon as possible after completion of each survey. Later the figures in more detail are included in the annual reports of the Division.

### LOCAL AND SPECIAL SURVEYS

Landings at certain important United States ports.—Statistics of the lands of aquatic products at the principal New England ports (Boston and Gloucester, Mass., and Portland, Maine) are obtained in a

similar manner. An agent is permanently stationed at Boston, Mass., and another is assigned to the ports of Gloucester, Mass., and Portland, Maine. Their duties include the obtaining of figures daily on the quantity of fish landed by each fishing vessel, the value of such fish landed, information concerning the date of departure and arrival of the vessel, and they also indicate the grounds from which the fish were taken and gear used in their capture. These data are forwarded to the Bureau, where compilations are made. Products of American fisheries received duty free at Boston and Gloucester, Mass., and Portland, Maine, from the treaty coasts of Newfoundland, Magdalen Islands, and Labrador are included in the landings at these ports; however, they are not included in the catch in sectional fishery surveys of the New England States unless they represent a catch by United States vessels. Statistics of these landings are released monthly and annually in bulletin form and detailed data are published in the annual reports of this Division. Data on the landings at Boston, and Gloucester, Mass., have been collected annually since 1893, and those for Portland, Maine, since June 1915. Some data are available for Boston and Gloucester prior to 1893.

Statistics of the landings of fish at Seattle, Wash., are collected by the Bureau's agent in that city. Landings are classified as those made by United States fishing vessels and those received by Seattle wholesale dealers. The landings credited to United States fishing vessels are made by vessels operating distinctly as primary fishing units, usually in the offshore fisheries, while those credited as received by wholesale dealers are usually products of the shore fisheries collected mainly from points in Puget Sound and do not include fish received from Alaska or Canada, or landings made by the halibut fleet. Statistics of these landings at Seattle are released monthly and annually in bulletin form and detailed data are published in the annual reports of this Division. Statistics of the landings by fishing vessels at Seattle have been collected since June 1915 and certain data on products received by Seattle wholesale dealers since December 1915.

products received by Seattle wholesale dealers since December 1915.

Atlantic mackerel fishery.—Statistics on the catch by the Atlantic mackerel fleet are obtained by combining the figures of mackerel landed at Boston and Gloucester, Mass., and Portland, Maine, with those obtained by Bureau agents, who in recent years have been stationed at other Atlantic ports where mackerel are landed. These agents obtain data on the volume of mackerel landed in a manner similar to that used to obtain figures on the landings by fishing vessels at the three New England ports. The figures include only the catches made by purse seine and drift gill net craft and are not complete for craft of under 5 net tons' capacity using this type of gear. Statistics of this fishery appear only in the annual reports of this Division, although the landings at the principal New England ports appear in the monthly and annual bulletins published for those ports. Statistics of this fishery are available from 1905 to 1937, inclusive.

Shad and alewife fisheries.—Owing to the importance of the Hudson and Potomac Rivers in the production of shad, surveys for statistics of the catch, value of the catch, and operating units are made annually. On the Potomac River similar statistics also are obtained for the alewife fishery. Much of the data required for these surveys are available from the State fishery agencies.

Statistics of the shad and alewife fisheries are not published separately in bulletin form, but a summary of the year's activities is

published in the annual reports of the Division.

Statistics of the shad fishery of the Hudson River are available for 1896, 1897, 1898, 1901, 1904, 1910, and from 1915 to 1937, inclusive, while data for the shad fishery of the Potomac River are available for 1896, 1901, 1904, 1909, 1915, and from 1919 to 1937, inclusive. Statistics of the alewife fishery of the Potomac River are available for 1896, 1909, 1915, and from 1919 to 1937, inclusive.

Pacific halibut fishery.—Statistics of the Pacific halibut fishery are obtained by the Bureau's agent in Seattle, aided by Bureau representatives in Alaska and the International Fisheries Commission. The fleet classification has been arbitrarily applied by including in the "Washington fleet" all United States and Alaska vessels that land more than half of their catch in that State. All other United States and Alaska vessels of the halibut fleet are included in the "Alaska fleet." Monthly and annual statistical bulletins are available on this fishery, being published along with the statistics of the landings of fishery products at Seattle, Wash., and detailed statistics are published in the annual reports of the Division. Statistics of the landings of halibut at Pacific coast ports have been collected since 1925.

Canned fishery products and byproducts.—Beginning in 1921, the Bureau has made annual surveys for statistics of the canned fishery products and byproducts industries of every section. These are begun the first week in January of each year for statistics of the production in the preceding year. The surveys usually occupy 6 to 9 weeks' time. During this period the Bureau obtains by mail, so far as possible, the production of canned fishery products or byproducts from each plant in the United States engaged in this business. Where it is impossible to obtain reports by mail the report is obtained by personal visit by the Bureau's agents. They obtain statistics of the production and value of the production for each commodity. Statistics of the canned fishery products and byproducts produced in Alaska are received on the same statements obtained by the Bureau that include statistics of general fishery operations.

An annual statistical bulletin is issued on this trade, and detailed statistics of the output are published in the annual reports of the Division. In addition to the data obtained on the output of these products annually since 1921, data also usually were obtained prior

to 1921 for the years the various sections were surveyed.

The value shown for canned products constitutes the gross amount received by the packer at the production point, no deductions being

made for commission or expenses.

Packaged-fish trade.—Complete statistics of the annual production and value of fish packaged in the United States are obtained as a part of the survey for the statistics of the canned fishery products and byproducts industries. These statistics are released in bulletin form annually and detailed statistics are published in the annual reports of the Division. Statistics of the production of packaged fish are available for 1926 and the years from 1928 to 1937, inclusive.

Cold-storage holdings of fish.—An arrangement has been made with the Bureau of Agricultural Economics, Department of Agriculture, whereby statistics of the cold-storage holdings of the various species of fish, by sections of the United States are furnished to this Bureau monthly. Included with statistics of the holdings are statements of the quantity of the various species of fish frozen and also the holdings of certain cured fish. Bulletins showing these statistics are issued monthly as well as annually, and detailed statistics are published in the annual reports of this Division. Statistics of cold-storage holdings of fishery products have been published since 1917 and data on quantities of fish frozen, for the years from 1920 to 1925, inclusive, and

from 1928 to 1937, inclusive.

Sponge market, Tarpon Springs.—A large proportion of the total output of sponges in Florida is handled through the sponge exchange at Tarpon Springs. In view of this, the Bureau has obtained from a representative of the exchange annual statistics of the quantity and value of the sponges, by variety classifications, handled through it annually. Statistics of the quantity of sponges handled through the exchange are not published in bulletin form, but a summary of the year's activities is published in the annual reports of this Division. Statistics of the transactions on the sponge exchange are available for 1913, 1914, and for the years from 1917 to 1937, inclusive.

Foreign fishery trade. Statistics of the foreign fishery trade are obtained from compilations made by the Bureau of Foreign and Domestic Commerce, Department of Commerce. Statistics of all known fishery products imported or exported have been assembled in one table and published annually in the reports of the Division in recent years. For earlier years they are available in the reports of the Bureau of Foreign and Domestic Commerce, the Bureau of Statistics, the Department of Commerce and Labor, or the Treasury

Department.

# PRACTICES AND TERMS

Certain practices and terms of importance used in the compilation

of fishery statistics are explained below.

Days absent.—In computing "days absent" for vessels landing fares at the various ports, the day of departure and the day of arrival are included; thus a vessel leaving port on the 8th of the month and returning on the 15th of the month will be shown as being absent

Operating units.—Operating units as referred to in this document include persons engaged in the fisheries, and fishing craft and gear

employed.

Vessel.—The term "vessel" refers to a craft having a capacity of

5 net tons or more.

Boat.—The term "boat" refers to a craft having a capacity of less than 5 net tons.

Incidental catch.—The term "incidental catch" refers to the catch of certain species by a type of gear which ordinarily does not capture

such species.

Percentages.—Percentages are usually shown as whole numbers. Fractions of percents are dropped if less than five-tenths, and the percentage is raised to the next higher integer if the fraction is greater than five-tenths. If the fraction is exactly five-tenths, the integer is raised or lowered to make it an even number.

Converting.—Many of the figures shown in the statistical tables published herewith have been converted to thousands of pounds or dollars. In making these conversions the largest number from which a group of items is computed is raised or lowered to the nearest thousands place. If the number ends in an even 500, the thousands integer is raised or lowered to make it an even number. The individual items are changed to conform to the total thus obtained.

Confidential data.—The statistical data collected by the Division are confidential and are not released except by approval of the Washington office. Statistics of production of wholesale and manufacturing firms are published only for commodities or geographical areas where the production of three or more concerns may be grouped. Every effort is made to publish only those figures which will not reveal individual enterprise.

CONVERSION FACTORS

It is the policy of the Bureau to show the detailed catch figures of all products in pounds for the sake of uniformity and for purposes of comparison. Following such a policy presents certain problems. In the case of fish there is little difficulty since in very rare instances are such products reported in units of measure other than pounds. For shellfish, however, the units of measure may be bushels, sacks, barrels, or thousands of shellfish, gallons of meats, etc. These many units make standardization difficult, but when coupled with the wide variation in the requirements or definition of some of these units in the various States the problem becomes even more complex.

All bivalve mollusks are reported in pounds of meats in the detailed catch tables presented in this report. In addition, there are included supplementary tables for most of the sections, which give data on the production in bushels. These supplementary tables also give the production of certain other shellfish, such as crabs, in number.

Oysters.—Probably the greatest problem in presentation of fishery statistics in uniform units of measure is in the case of oysters. Usually the production of oysters on the Atlantic and Gulf coasts is reported to Bureau agents in bushels; and prior to the data obtained for the year 1930 conversion from bushels to pounds of meats was effected on the basis of a uniform yield of 7 pounds of meats to the bushel. However, more recent investigations have shown considerable variation from this figure. There follows a table which gives the results of these studies of the measures used for oysters in the various States and of the average yields per bushel. This table presents the factors that have been used in the oyster statistics given in this report.

Measures and yields of oysters

	Capacity			Market	oysters
State	of State bushel	Variation from U.S. standard bushel		Yield per State bushel	Yield per standard bushel
Massachusetts Rhode Island Connecticut New York New Jersey Delaware Maryland Virginia North Carolina South Carolina Georgia Florida Alabama Mississippi Louislana Texas	2, 150, 4 2, 150, 4 2, 150, 4 2, 150, 4 2, 257, 3 2, 257, 3 2, 261, 5 3, 003, 4 2, 801, 9 4, 071, 5	+106, 9 +106, 9 +651, 1 +853, 0 +651, 5 +1, 921, 1 +3, 193, 5 +1, 063, 7 +675, 8 +675, 8 -2, 0 +449, 6		Pounds of meats 6.57 7.05 7.70 6.05 7.00 6.05 7.98 6.06 6.852 5.87 6.21 5.49 5.13 4.95 4.09 5.64	Pounds of meats 6.57 7.05 7.70 7.00 5.76 6.67 4.59 4.34 4.24 3.10 2.50 3.67 3.90 3.78 4.09 4.49

Other mollusks.—The following table shows the conversion factors for various mollusks, other than oysters, used in this report:

Average yields of certain mollusks in pounds of meats per State bushel

State	Clams, hard	Clams, soft	Clams, surf	Clams.	Mus- sels. sea	Peri- winkles and cockles	Scal- lops, bay	Scal- lops, sea	Conchs
Maine New Hampshire	11	15 15	 		12	18	6	6	· · · · · •

Menhaden	To convert number of fish to weight in pounds, multiply by 0.6.
Pollock, salted	To convert to fresh-gutted weight, multiply by 1.90.
Sponges, dried (Florida):	·
Large wool	To convert number of bunches to weight in pounds, multiply by 7.
Medium and small wool	To convert number of bunches to weight in pounds, multiply by 3.
Wool rags	To convert number of bunches to weight in pounds, multiply by 4.5
Grass	To convert number of bunches to weight in pounds, multiply by 1.5.
Wire and yellow	To convert number of bunches to weight in pounds, multiply by 2.

# COMMON AND SCIENTIFIC NAMES OF FISHERY PRODUCTS

In order to prevent misunderstanding in the use of common names employed in the tables and discussions, the following list of common and scientific names is given:

Common and scientific names of the commercial fishery products caught in the United States and Alaska

Common name as shown in Bureau reports	Other common names	Scientific names
AlbacoreAlewifeAmberjack	(See tuna). (Branch herring, wall-eyed or big-eyed herring. (Blueback, glut herring	Germo alalunga. Pomolobus pseudoharengus. Pomolobus estivalis. Seriola species.
·		Engraulis mordax. Anchoriella delicatissima. Anchoriella compressa. Pomacanthus arcuatus. Holacanthus isabelita.
Black bass	{Smallmouth bass   Largemouth bass	Sphyraena argentea. Micropterus dolomieu. Micropterus salmoides.
Blue runner or hardtall	Tailor Pike perch, blue pickerel (Canada) Runner	Pomatomus saltatriz. Si iostedion plaucum. Caranz crysos. (Sarda sarda.
BowfinBuffalofish		Sarda chiltensis. A mia calva. Ictiobus species.
ButterfishBurhot	Lawyer, ling Coalfish, crab sater, cobia Rock bass	Lota maculosa.

Common name as shown in Bureau reports	Other common names	Scientific names
Carp	German carp	Cyprinus carpio.
Catfish and bullheads		Ameiurus species. Ictalurus species. Leptops olivaris.
CeroChub	Painted mackerel Tullibee in Canada; longjaw, bluefin, blackfin in United States.	Scomberomorus regalis. All Leuchichthys except artedi (in Great Lakes).
Cigarfish	Scad	Decapterus punctatus.   Leucichthys artedi (Lake Erie only).   Gadus macrocephalus (Pacific coast).
Cod	Codfish	Gadus callarias (Atlantic coast).
Crappie	Black crappie, strawberry bass, calico bass.	Pomoxis sparoides.  Caranz hippos.
Crevalle	Crocus, hardhead Chogset, blue perch, bergall	Micropogon undulatus. Tautogolabrus adspersus. Brosme brosme.
Cusk Dolly Varden trout Dolphin	Salmon trout, bull trout	Salvelinus parkei. Coryphaena hippurus.
BlackRed	Channel bass, redfish, spotted bass	Pogonias cromis. Sciaenops ocellatus.
Common		Anguilla rostrata. Leptocephalus conger.
Flounder: Gray sole		Glyptocephalus cynoglossus. Pseudopleuronectes dignabilis.
Yellowtail and dab		{Limanda ferruginea. Hippoglossoides platessoides. Pseudopleuronectes americanus.
Fluke "Sole"		Paralichthys dentatus. Pleuronectidae species (Pacific coast). Paralichthys californicus.
Unclassified		Pleuronectidae species. Cypsilurus californicus.
Frigate mackerel Garfish Gizzard shad	"Boo Hoo". Nanny shad, mud shad	
GoldfishGoosefish	Sand perch.	Carassius auratus.
Grayfish	Dogfish   Spiny dog   Smooth dog	Squalus acanthias. Mustelus mustelus.
Grouper	"Sea bass"	Legimente in species.   Myceteroperca species.
Haddock	Squirrel hake, Boston hake, ling, black hake, mud hake, Merluccio	Melanogrammus aeglefinus, Urophycis species (Atlantic coast).
Halibut.	Merluccio	Merluccius productus (Pacific coast). Hippoglossus hippoglossus.
Hardhead Harvestfish	Starfish, dollarfish, pappyfish, butter-fish (N. C.).	Orthodon microlepidotus (Pacific coast). Peprilus alepidotus.
Herring: Lake	Herring	Leucichthys artedi (Great Lakes, except Erie).
Round		Elrumeus sadina. {Clupea harengus (Atlantic coast).  Clupea pallasii (Pacific coast).
Herring smelt	Sea smelt. Tailor shad, skip.	Argenting situs.
Hogfish Horse mackerel	Capitaine, perro perro	Lachnolaimus maximus (Florida).
Jewfish	Atlantic—(See tuna.)  [King mackerel, cerro	Promicrops itaiara. (Scomberomorus cavalla (Atlantic coast).
Kingfish	Little roncador, croaker	Scomberomorus cavalla (Atlantic coast). (Scomberomorus regalis (Atlantic coast). (Tenyonemus lineatus (California). Menticirrhus species.
King whiting Lake trout Lamprey	Northern whiting, kingfish, sea mink	Cristivomer mamaycush. Petromyzon marinus.
Launce. "Lingeod"	Sand eel, lant, sand launce. Cultus cod, blue cod, buffalo cod, ling.	Ammodytes americanus. Ophiodon elongatus. (Scomber scombrus (Atlantic coast).
Mackerel		Scomber diego (Pacific coast).

# U. S. DEPARTMENT OF COMMERCE

HARRY L. HOPKINS, Secretary

# BUREAU OF FISHERIES

CHARLES E. JACKSON, Acting Commissioner

Administrative Report No. 38

# PROPAGATION AND DISTRIBUTION OF FOOD FISHES

FISCAL YEAR 1939

By GLEN C. LEACH, M. C. JAMES and E. J. DOUGLASS

APPENDIX IV TO REPORT OF COMMISSIONER OF FISHERIES FOR THE FISCAL YEAR 1939

UNITED STATES
GOVERNMENT PRINTING OFFICE
WASHINGTON: 1940

#### ADMINISTRATIVE REPORT SERIES

Since the advent of the Administrative Report Series, considerable confusion has arisen concerning its system of numbering the separates composing it. much as the Reports of the Divisions vary in order from year to year, many have found their designations as "Appendix No. I, II, III, or IV" very confusing. To relieve this, it has been decided to number them as "Administrative Report No.—." Inasmuch as 20 separates had already been printed in this series before starting the numbers, it was deemed advisable to begin the numbering with Administrative Report No. 21. Of course, numbers cannot be printed on those already off the press, but for the information of those who wish to know what the first 20 were, they are numbered for filing purposes as follows:

No. 1. Report, Commissioner of Fisheries, 1931.

No. 2. Alaska Fishery and Fur-Seal Industries, 1930.

No. 3. Fishery Industries of the United States, 1930.

No. 4. Progress in Biological Inquiries, 1930. No. 5. Propagation and Distribution of Food Fishes, 1931.

No. 6. Report, Commissioner of Fisheries, 1932.

No. 7. Alaska Fishery and Fur-Seal Industries, 1931.

No. 8. Fishery Industries of the United States, 1931.

No. 9. Progress in Biological Inquiries, 1931.

No. 10. Propagation and Distribution of Food Fishes, 1932.

No. 11. Alaska Fishery and Fur-Seal Industries, 1932. No. 12. Progress in Biological Inquiries, 1932. No. 13. Fishery Industries of the United States, 1932.

No. 14. Propagation and Distribution of Food Fishes, 1933.

No. 15. Fishery Industries of the United States, 1933.

No. 16. Alaska Fishery and Fur-Seal Industries, 1933.

No. 17. Progress in Biological Inquiries, 1933.

No. 18. Propagation and Distribution of Food Fishes, 1934.

No. 19. Alaska Fishery and Fur-Seal Industries, 1934. No. 20. Fishery Industries of the United States, 1934.

Note that the last Commissioner's Report was for 1932. Since then its place has been taken by a reprint from the Report of the Secretary of Commerce under the title "Bureau of Fisheries." Inasmuch as it is no longer a Bureau publication, it is not numbered; but it will be supplied to any who request the Report of the Commissioner for any year since 1932.

### INTRODUCTION

Summary, by States, of the distribution of fish, fiscal year 1939

Distribution operations

Aquarium.....

594

595

596

555

In announcing the gross production of 8,024,540,685 fish and eggs at Federal fish hatcheries during the fiscal year 1939, the Bureau recognizes that the significance of such a contribution is obscured without further analysis in the form of a report of hatchery production in terms of pounds of fish. However, no such treatment can be followed in handling the billions of fry and eggs of commercial marine species, but it is expected to place in operation during the fiscal year 1940 a system of weighing all the game fish distributed. Again, the production of a few hundred thousand fry or fingerlings of a species which is subject to intense fishing pressure, such as certain species of Pacific salmon, is of greater importance than the distribution of millions of fish of lesser economic value, such as the yellow perch.

It may well be asked why these figures are not reversed and maximum production maintained with the varieties which exhibit the greatest need for restorative measures. This question can be answered by pointing out that, broadly speaking, artificial propagation must be

Administrative Report No. 38, Appendix IV to the Report of the U. S. Commissioner of Fisheries for the fiscal year 1939. Approved for publication April 23, 1940.

geared to the egg supply, and a depleted species is its own limiting

factor upon the scope of artificial replenishment measures.

Fish-cultural technology extends from the production of an entirely "synthetic" fish, such as game trout, to a process of byproduct recovery as exemplified in the propagation of shad. A brook trout may be hatched from an egg obtained from a domesticated brood stock held at a private commercial hatchery and may be reared to a size permitting its capture by the angler immediately after its release from the hatchery. This is a synthetic but definite increment of a recreational resource.

On the other hand, migrating shad, when caught for market, may be carrying over 30,000 mature eggs which can be incubated in a hatchery and released as fry. The survival ratio of these fry cannot now be accurately determined, but it is known that without the intervention of the hatchery, the reproductive contribution of the parent

fish would be zero.

Hatcheries have failed to stem the depletion of certain species, such as the whitefish, but their role as an elemental factor in conserving the majority of the food and game species is widely conceded. The administration of this activity requires attention to the methods and technique of hatching, rearing, feeding, and transporting fish; to the maintenance and upkeep of the physical plant and equipment; and to the construction of new facilities. The year under review has shown tangible progress in all these aspects. While it has been possible to continue the services rendered to the general public by the stocking of public waters, much of the increased production attained in recent years has been diverted to maintaining the stock of fish in areas under direct Federal ownership or control.

Complete transition to this type of activity is not anticipated, however, as long as the present unbalanced ratio between fishing demand and fish populations in State waters exists. The succeeding tabulations and comments are presented with the purpose of clarifying the significance of the various types of fish-cultural functions carried

on by the Bureau.

# SPECIES PROPAGATED

During 1939 there were handled at the hatcheries and rescue stations 47 species, the majority of which are fresh-water types. No attempt has been made to propagate a dozen or more important food fishes which are found in the coastal waters. No practicable methods for propagating certain of these forms have been developed, and there is further doubt as to whether results would be sufficiently valuable to warrant the effort.

In addition to the varieties listed in the table, there are propagated forage fishes comprising some half dozen species of minnows and shiners. These are utilized as food for bass, etc., at the hatcheries and are not available for general distribution or listed in the pro-

duction records.

No carp, humpback salmon, or Atlantic salmon were handled during the year although these forms were propagated previously. The carp were dropped because of the desire to devote available funds to the propagation of more valuable forms. The "off year" for humpback salmon made it impracticable to obtain eggs of this species and no Atlantic salmon eggs were available from any source. Kentucky, or spotted bass were distributed for the first time, and

the hatching of mackerel was resumed on a limited scale.

The hatchery records reveal interesting facts regarding the popularity of different game species. There appears to be no "All-American" fish, but the largemouth bass most closely approaches this classification. The popularity of the trouts is sectional, with the species native to the different regions rated highest in popularity in their respective sections. The smallmouth bass is highly popular although somewhat restricted in range and has, in the past, presented a production problem which is being rapidly overcome.

The commercial species which have been distributed are those which are most amenable to artificial propagation and are not necessarily

those which are of the highest economic value.

```
Catfishes (Siluridae):
    Catfish (Leptops olivaris).
    Spotted channel catfish (Ictalurus punctatus).
    Bullhead (Ameiurus nebulosus).
Buffalofish (Catostomidae): Common buffaloes ((Ictiobus sp.).
Shad and herring (Clupeidae):
    Shad (Alosa sapidissima).
    Glut herring (Pomolobus aestivalis).
Whitefishes and Lake herring (Coregonidae):
    Common whitefish (Coregonus clupeaformis).
    Lake herring, cisco (Leucithys sp.).
Salmons and trouts (Salmonidae):
    Chinook, king, or quinnat salmon (Oncorhynchus tschawytscha).
Chum salmon (Oncorhynchus keta).
    Coho salmon, silver salmon (Oncorhynchus kisutch).
    Red Salmon, sockeye, or blueback salmon (Oncorhynchus nerka).
    Landlocked sockeye salmon, silver trout (Oncorhynchus kennerlyi).
    Steelhead trout (Salmo gairdnerii).
    Landlocked salmon (Salmo sebago).
    Rainbow trout (Salmo irideus).
    Black-spotted trout, cut-throat trout (Salmo clarki).
    Brown or Loch Leven trout (Salmo fario var.).
    Lake trout, mackinaw trout (Cristivomer namayensh).
    Brook trout (Salvelinus fontinalis).
    Golden trout (Salmo agua-bonita).
Grayling (Thymallidae): Montana grayling (Thymallus montanus).
Pikes (Esocidae): Pike and pickerel (Esox sp.).
Sunfishes (Centrarchidae):
    Crappie (Pomoxis annularis and P. Sparoides).
    Largemouth blackbass (Micropterus salmoides).
    Smallmouth black bass (Micropterus dolomieu).
    Kentucky bass (Micropterus pseudoplites).
    Rock bass (Ambtoplites rupestris).
    Warmouth bass (Chaenobryttus gulosus).
    Bluegill sunfish (Lepomis incisor).
    Green sunfish (Lepomis cyanellus).
    Redbreasted bream (Lepomis auritus).
    Red-eared sunfish (Lepomis heros).
    Common sunfish (Lepomis gibbosus).
Mojarras de rio (Cichlidac):
    Rio Grande perch (Herichthys cyanoguttatus).
Perches (Percidae):
    Pike Perch (Stizostedion vitreum).
    Yellow perch, ringed perch (Perca flavescens).
White basses (Serranidae):
    White bass (Roccus chrysops).
    Striped bass (Roccus saxatilis).
    White perch (Morone americana).
```

Cods (Gadidae):

Cod (Gadus callarias).

Haddock (Melanogrammus aeglefinus).

Pollock (Pollachius virens).

Mackerel (Scombridae): Common mackerel (Scomber scombrus).

Flounders (Pleuronectidae): Winter flounder (Pseudopleuronectes americanus).

Lobster (Homaridae): Lobster (Homarus americanus).

Summary, by species, of the output of fish and fish eggs during the fiscal year ending June 30, 1939

### PRODUCTION

The 1939 output of 8,024,540,685 fish and eggs was an insignificant reduction from the production for the previous year of 8,121,131,985. The former figure presents a yield derived almost 100 percent from the hatcheries, in comparison with the situation during previous years when an average of over 50 million fish was obtained from rescue and salvage operations. The negligible number of salvaged fish in the 1939 record is responsible for the noticeable decline in the distribution of fingerlings and larger fish. These amounted to 84,332,955 in comparison with 119,184,705 for 1938. All the fish formerly collected from the overflow areas of the upper Mississippi River were from 4 to 6 months old, and this stock must hereafter be replaced by fish reared in the hatchery ponds.

Sixteen varieties were propagated in larger numbers than during the previous year; among them the important chinook salmon, shad, lake trout, grayling, largemouth and smallmouth bass, pike perch,

cod and haddock.

There was included in the total a production of 102,366,985 game and pan species, a percentage of approximately 1.3. As has been previously asserted, practically all the species propagated by the Bureau are sought by anglers to some degree. However, in designating "game and pan species" the Bureau is guided by the classifications of the State fisheries laws and by the determination of whether a given species supports an extensive commercial fishery. If such is the case, it is listed as a non-game species.

The most important point to be considered in analyzing the production records is the difference between gross and net output. The aggregate production of the individual hatcheries is greater than the actual or net plantings of fish because of the fact that transfers are made between different stations. The station hatching and shipping fish must of necessity be given credit for this production; and the station which subsequently rears and plants the fish is likewise entitled to credit for the number distributed. It is further evident that this involves a duplication in the summary or grand total. During 1939 there were 833,335 fish transferred between the stations. Deducting this from the grand total by species leaves a net distribution of 2,198,905,280 fish and 5,824,802,070 eggs as an actual increment to the fish population resulting from the Division's activities. For the same reason the record of distribution by States (see p. 596) will not check in its totals with the summary by species.

While extensive repair and improvement work was under way throughout the year at most of the stations, in very few instances did this interfere materially with the fish production. The Bureau has not as yet achieved its objective for the production of a greater proportion of trout and bass of legal size. Costs, both for fish food and personnel, as well as the increased expense of distributing larger fish, remain the chief limiting agents.

### CONSTRUCTION ACTIVITIES

Shortly before the start of the fiscal year the Division received an allotment of \$808,500 from the Public Works Administration and \$544,856 from the Works Progress Administration. The former was intended largely for the procurement of materials and supplies, while the latter was solely for labor. These amounts were reallocated to the various projects as listed in the following table:

Stations receiving P. W. A. and W. P. A. allotments during the fiscal year 1939

¹ N. Y. A. labor furnished.

Certain supplementary W. P. A. allotments were received later in the year, increasing the amount available for labor. The work involved replacement of pipe lines; complete construction of new water-supply systems; construction, repair, and improvement of buildings; construction of ponds; installation of new equipment; and general landscaping. In some instances there was a 100-percent increase in the productive capacity of a station through such improvements.

The principal development of an entirely new nature was the construction of a pondfish hatchery at the Roy Inks Dam, on the lower Colorado River in Texas. The site was furnished by the Lower Colorado River Authority and construction was supervised by the Bureau. It was financed by a portion of the P. W. A. allotment and by the assignment of N. Y. A. labor. At the close of the year this project was virtually complete and some of the ponds were stocked with fingerling bass. The output of the establishment is planned for distribution in the series of reservoirs created on the Colorado River.

Noticeable improvements were effected at the Fort Worth (Tex.) station, where an additional tract of land was donated by the city of Fort Worth and utilized for the development of additional ponds. The Charlevoix (Mich.) Hatchery, which had been closed since 1933, was entirely rehabilitated and equipped for the rearing of lake trout fingerlings. In several instances State W. P. A. projects were also in effect and made possible additional improvements. An outstanding

example of this was at Guttenberg, Iowa, where initial work on a large-scale pondfish hatchery, within the Upper Mississippi River

Wildlife and Fish Refuge, was undertaken.

Curtailment of the scope of the Civilian Conservation Corps resulted in some restriction on the construction work prosecuted by this agency for the Bureau. A limited number of assignees were held on at Lamar, Pa., but the C. C. C. development program at the York Pond (N. H.) station was terminated, although the work was continued by the utilization of other funds.

At Arcadia, R. I., development of a bass hatchery by the Bureau and the Soil Conservation Service of the Department of Agriculture continued. This had been originally started as a recreational project under the Farm Security Administration and the major part of the construction has been continued by the successor to that agency. The Bureau contributed supervision and limited funds for the purchase of materials and equipment. Due to shortage of funds the work was suspended at the close of the year with the expectation that it would be resumed early in the fiscal year 1940.

The National Park Service secured an allotment of emergency funds for the construction of a new hatchery at Creston, near Kalispell, Mont. This establishment is intended to replace the obsolete Glacier Park fish hatchery, although it is located outside the boundaries of the park itself. The work, which was started in the spring, was being prosecuted by the National Park Service, with the Bureau represented in an advisory capacity. The operation of this hatchery is to

be taken over by the Bureau upon completion.

In addition to the improvements made possible by direct cash allotments to the Bureau, the Appropriation Act for 1939 carried the sum of \$155,000 providing for the construction of new hatcheries in Kansas, North Dakota, Minnesota, and Ohio. Early in the year a suitable site was located at Valley City, N. Dak., and construction work was started in the late fall. At the close of the year the hatchery was approximately 75 percent completed, although not in readiness for operation. At this point a State W. P. A. project was of material help in securing maximum returns from the appropriation available.

After a careful survey the three remaining hatcheries were designated for sites at Hebron, Ohio, Farlington, Kans., and New London, Minn. Various difficulties were encountered in acquiring clear titles to these sites, with resultant delay in starting actual construction. However, at the close of the year preparations were being made to initiate the construction phase at each of these locations, although no actual development had been undertaken. The appropriations made for these hatcheries were continued available during the fiscal year 1940.

The construction activities summarized above have resulted not only in actual increase of hatchery facilities but have also made it possible to take care of maintenance and rehabilitation work, the need for which has been appropriately according to the property of the property of the property of the property of the property of the property of the property of the property of the property of the property of the property of the property of the property of the property of the property of the property of the property of the property of the property of the property of the property of the property of the property of the property of the property of the property of the property of the property of the property of the property of the property of the property of the property of the property of the property of the property of the property of the property of the property of the property of the property of the property of the property of the property of the property of the property of the property of the property of the property of the property of the property of the property of the property of the property of the property of the property of the property of the property of the property of the property of the property of the property of the property of the property of the property of the property of the property of the property of the property of the property of the property of the property of the property of the property of the property of the property of the property of the property of the property of the property of the property of the property of the property of the property of the property of the property of the property of the property of the property of the property of the property of the property of the property of the property of the property of the property of the property of the property of the property of the property of the property of the property of the property of the property of the property of the property of the property of the property of the property of the property of the property of the property of the p

has been accumulating over a number of years.

# COOPERATION WITH OTHER CONSERVATION AGENCIES

Much of the most effective work performed during the year has been in cooperation with one or more other public or private agencies whose functions relate to the conservation of fish life. Such coordination has been applied in matters as simple as the delivery of a consignment of fish or as complex as the development of a program for preserving the salmon run in the Columbia and the Sacramento Rivers, where the survival of the species is threatened by huge dam construction projects.

In working out the details of these various joint undertakings, frequent contact has been maintained with Federal departments, bureaus and agencies, with more than 30 State conservation departments, with several municipalities and county governments, and with innumerable sportsmen's and conservation organizations of a semi-public nature. The mechanism for coordination has consisted of broad general agreements, such as have been set up with the United States Forest Service, the National Park Service, the Tennessee Valley Authority, and several of the States. There have also been specific written agreements covering individual problems or projects as well as informal understandings reached by conference between field employees or headquarters officials. In the latter case the meetings of the National Planning Council of Fish and Game Commissioners have afforded an opportunity for channeling Federal and State fish-cultural activities toward maximum efficiency and utility.

As an indication of the manner in which conservation activities have been prosecuted on a joint basis, there are cited below various instances and examples. These do not present the full scope of such undertakings but space limitations necessitate many omissions.

The relationships maintained with the counties of Monroe and Onondaga, N. Y., for the purpose of propagating and distributing fish in local waters, have served as a model for a similar undertaking with the city of Danville, Va. Initial steps have been taken whereby the Bureau will supply fish for the maintenance of angling in lakes and streams developed by the city for hydroelectric purposes. The city will, according to plans, meet the costs of developing necessary facilities and caring for the fish.

The exchange of eggs and fish has been of material benefit, particularly in Michigan, Minnesota, and in some of the Western States, such

as Oregon.

In the Tennessee Valley area three-way agreements between the Bureau of Fisheries, the Tennessee Valley Authority, and the States of Alabama, Tennessee, and North Carolina have been made effective or are being negotiated. The Tennessee Valley Authority had practically completed on June 30 a large pondfish hatchery on the Elk River in Alabama, and the Bureau was making arrangements to establish personnel and take over the operation. This is in addition to the hatchery already operated at Norris, Tenn., which is scheduled for enlargement. The fish produced at these facilities are to be distributed by the States in that part of the Tennessee Valley area which is included in the respective State boundaries.

In addition to cooperating with the National Park Service in the stocking of National Park waters, a brief reconnaissance and survey was made on the Chesapeake and Ohio Canal on the Potomac River above Washington, D. C. This property had been acquired by the National Park Service for recreational purposes, and it is expected that angling will be one of the outstanding recreational features. Agreement has been formulated whereby the Bureau will work with

the Park Service in building up the angling.

In view of the tremendous responsibility of the Forest Service, of the Department of Agriculture, for the maintenance of fishing in the national forests, there has been need for unusual cooperation with that agency. A new trout-rearing unit was under construction in the Alleghany National Forest in Pennsylvania, in accordance with plans developed and approved by the Bureau, with the expectation that

the unit would be operated by this Bureau upon completion.

The North Dakota Fish and Game Department donated to the Bureau the site for the new hatchery at Valley City, and further local assistance was received by the donation of pipe, a pump, etc. The North Carolina Fish and Game Department has contacted the Bureau freely and frequently relative to mutual problems, and it has been possible to render reciprocal assistance in the propagation of shad, the selection and inspection of hatchery sites for State development, and in the distribution of trout. A very large part of the production of the Marion (Ala.) station has been transported in State distribution trucks.

At St. Louis, Mo., the city officials have approved the construction, at no cost to the Bureau, of a modern administration and service building in the Forest Park hatchery. The series of ponds in the municipal park system was taken over by the Bureau for operation shortly before the start of the fiscal year 1939, and results have been

most gratifying.

The State of Minnesota exhibited splendid cooperative spirit in donating to the Bureau a tract of land, together with the water rights. for the proposed hatchery at New London, and made available the services of its surveyors and engineers in acquiring additional property. Local interests raised a sum of money for the purchase of some of the additional acreage needed for the hatchery. The same cooperative assistance was obtained in Kansas, where the State Fish and Game Department donated water rights to a State-owned lake which is to serve as the primary water supply for the hatchery ponds.

Ohio purchased and donated to the Bureau a splendid location for the new hatchery to be constructed in that State. In consideration of this courtesy the Bureau approved the relinquishment to the State of the Federal hatchery property at Put in Bay. However, such action requires Congressional sanction, and the necessary legislation

had not been passed at the close of the year.

Organized sportsmen's groups throughout the country have sought technical advice on stocking problems and have submitted many applications for fish to be reared in nursery ponds sponsored and maintained by these organizations.

# ASSIGNMENTS OF FISH AND FISH EGGS TO STATES, TERRITORIES, AND FOREIGN COUNTRIES

The transfer of approximately 166,000,000 fish and eggs to other fish-cultural agencies in the United States and its possessions was closely in line with the scope of such shipments in previous years. Forty States were the recipients of this form of Federal aid. number of cases the transfer was handled on an exchange basis, the Bureau being compensated by the State furnishing eggs or fish of needed species. The benefits in this procedure lie in the fact that many States were thus able to procure species which would be unobtainable from other sources. Also, where State hatchery facilities are limited in capacity, the Bureau's assignments have been the backbone of the States' stocking programs. Some lobsters were turned over to Maine for rearing in the new State rearing station. Flounder fry were allocated to New Jersey from the Woods Hole (Mass.) station. Nebraska received a few grayling eggs, which would have been difficult to obtain elsewhere.

The Bureau had a surplus of certain species in some areas and has established the policy of disposing of such surpluses to nearby States whenever possible. The assignments reported in the following table should not be confused with the listing of Distribution by States, since the latter also covers fish delivered on applications or planted directly by Bureau employees.

The shipment of fish and eggs to foreign countries has been an interesting but unimportant activity of the Division for many years. While such consignments have been furnished gratis from available hatchery stocks, no expense has been incurred in forwarding the shipments. During the past year an initial shipment of 250,000 lake trout eggs was sent to Peru, as a start on a program of establishing this species in Lake Titicaca. Due to insufficient time for the necessary preparation and scheduling of the shipment, the eggs were a total loss. Rainbow eggs were sent to England as a means of introducing new blood into the existent stocks of the species in that country. Rainbow trout eggs and fry were sent to Costa Rica and Colombia as an experiment, with little success. As usual, rainbow eggs were forwarded to Puerto Rico in line with plans to develop angling as a means of attracting tourists to that island.

There were additional inquiries from serveral other countries relative to securing some species of American fishes, but for various reasons no action was taken.

Shipments of fish and fish eggs to territories and foreign countries, fiscal year 1939

## TRANSFER OF EGGS BETWEEN STATIONS

The economy of concentrating upon egg production at 3 or 4 stations, from which shipments can be made to other points, has frequently been emphasized. This practice was continued throughout the past year and over 43 million eggs of 10 different species were transferred between various stations. The following table sets forth in detail all such transfers.

Transfer of eggs between stations, fiscal year 1939

#### STATION OUTPUT

The following list of producing units represents an increase of 6 stations over the previous year. The 1939 production was obtained from a total of 52 main stations and 46 substations located in 39 States. Although the output of each of these units is primarily intended for the restocking of waters in contiguous areas, the production of any of them may, nevertheless, reach 2 or 3 different States.

The Marianna (Fla.), Las Vegas (Nev.), Cohutta (Ga.), and Lyman (Miss.), stations, which were constructed during the fiscal year 1938, as authorized by the act of May 21, 1930, were among those that

contributed for the first time this season.

The Genoa (Wis.), unit, which is being constructed in the Upper Mississippi Wild Life and Fish Refuge, was completed to such an extent that three ponds, with an area of approximately 60 acres, were placed under production in the spring of 1939. During the month of June there were collected and distributed from these ponds approximately 2 million fingerling black bass. The Palestine (W. Va.) station, which is owned by the West Virginia Conservation Commission, was operated in cooperation with that agency for the stocking of waters in the western part of West Virginia, and therefore appears in the following summary. The Clark Fork (Idaho) unit was constructed as a W. P. A. project sponsored by the Idaho Fish and Game Department on land donated by the Bonner County

Sportsmen's Association. After being turned over to the Bureau on September 11, 1938, it was immediately placed on a productive basis. The Carpenter's Brook (N. Y.) station, which is operated in cooperation with the Onondaga County sportsmen, was nearly completed and an output of trout was attained.

Due to the development of the 9-foot channel in the upper Mississippi River, rescue operations were discontinued from the Lynxville (Wis.) and Homer (Minn.) stations. The latter unit was maintained

as a repair shop and supply depot.

Stations and substations operated and the output of each, fiscal year 1939

#### EGG COLLECTIONS

In spite of a slight reduction in hatchery output for 1939 the collections of eggs for that period exceeded the 1938 figure by some 355 million. This is explained in part by the fact that a considerable number of fingerlings, particularly of salmon, are being held for distribution during the succeeding fiscal year, and the 1939 distribution was in part achieved from the 1938 egg collections. The greatest increase was in the collection of cod eggs, which were increased by approximately 825 million, and in the pike perch work, where the increase was about 710 million. Mortalities in hatching these eggs may vary widely, with the consequent possibility of a reduction in the production of fry in spite of an increased take of eggs.

Comparison of egg collections, fiscal years 1938 and 1939

#### NOTES ON OPERATIONS

#### COMMERCIAL SPECIES

Pacific salmon.—It is recognized that the run of chinook salmon, which is the most valuable species of the Pacific salmon in the Columbia and Sacramento Rivers, is facing a very serious situation because of the construction of dams on these rivers. Millions of dollars are being spent by the Pacific Coast States and the Federal Government to maintain the run of this species. During the year 1939 the output of chinook salmon fingerlings from the Bureau's hatcheries was approximately 14 million over that of 1938.

In the Puget Sound territory, the Birdsview (Wash.) station handled fewer eggs and fish than during the previous season but reared the

greater percentage of its output to a larger size before releasing them. This recession was largely due to the fact that no humpback salmon eggs were taken, whereas last year 4.305,000 were collected during the largest run of this species in the Skagit River in 25 years. The output comprised 4 species of trout and 3 varieties of Pacific salmon. No chum salmon were propagated. Twenty small concrete rearing ponds which had been in use since the origin of the station were dismantled, and an entire new concrete pond system consisting of 8 ponds 13½ feet wide by 56 feet long was constructed. The capacity of each pond is about 250,000 2- to 3-inch fish. Cottage No. 1 was renovated and all other buildings repaired and painted. A new machinery shed 24 by 60 feet, with open front, was constructed for

use in storing station machinery and equipment.

The total number of eggs collected by the Clackamas (Oreg.) station and its auxiliaries amounted to approximately 22,700,000, as compared with 20,000,000 during the past year—an increase of nearly 12 percent. This total was due to the abnormally large collections of fall chinook salmon eggs at the Battle Creek and Mill Creek (Calif.) substations. The collection of spring chinook salmon eggs was below normal at both the Clackamas and Butte Falls units. The low collection of eggs at the latter point is ascribed to the late installation of the headrack across Rogue River, which was due to the late runoff of snow water from the upper sources of this stream. A new permanent rack and trap in Butte Creek yielded more than 11/2 million steelhead trout eggs. However, the collection of silver salmon eggs from this body of water proved a complete The Clackamas station supplemented its salmon work by handling brook and rainbow trout. The pond system at the Delph Creek rearing station was repaired, rearranged and enlarged. Construction of a frame hatchery building was started. At Clackamas the old combination workshop and dwelling was remodeled. laboratory building, 32 by 45 feet, for use by the Division of Scientific Inquiry, was practically completed. A chlorinating system was installed for the purpose of sterilizing the water supply before it enters the two reservoirs with the expectation that previous heavy mortality of fish would be eliminated. The two residences under construction at the Butte Falls station were completed during the year.

The development of the hatchery at Carson, Wash., was continued under the auspices of the P. W. A. and W. P. A. and with the cooperation of the United States Forest Service. This unit does not as yet have a pond system of sufficient capacity to rear its fish to a large size before releasing them. Plans have been drawn up for increasing the pond space. Chinook salmon and brook, rainbow, and black-spotted trout were handled during the year. All of the trout were assigned to the Forest Service for the stocking of waters under the

control of that agency.

Due to the development of the Bonneville Dam on the Columbia River, the Little White Salmon and Big White Salmon substations had to locate new seining grounds and clear the debris from such areas in order to facilitate the capturing of adult salmon. Nevertheless, the former station collected 20,443,000 chinook salmon eggs, which is a normal take, and the latter unit secured 18,250,000 eggs of this species, which was its largest collection since the season of 1932. While the Little White Salmon station was solely engaged in the

propagation of chinook salmon, the Big White Salmon station augmented its salmon work by handling brook and rainbow trout. New buildings were constructed at both points and numerous repairs

made to old structures.

The Quinault (Wash.) station collected its quota of sockeye salmon eggs for hatching, which is 2,000,000, and secured an additional 200,000 for transfer to the Washington State Fisheries Department. This unit also handled chinook and silver salmon and steelhead, rainbow, brook, and blackspotted trout. The eggs for all species propagated, except the latter two, were collected locally. Approximately 3,350,000 eggs were handled and the resultant fish were all reared to fingerlings before being liberated. The Humptulips trap, which is located on the West Fork of Humptulips River, was completed and operated during the chinook salmon and steelhead trout runs. Other construction work consisted of the following: Food room rebuilt, hatchery building reroofed, new office in hatchery constructed, large cold-storage room built, new concrete walks and stairways poured, and grounds landscaped.

The major fish-cultural activity at the Duckabush and Quilcene (Wash.) substations was the propagation of chum salmon. Due to stream-improvement work at the mouth of the Big Quilcene River at the height of the spawning season of the early run, the latter station was unable to secure any chum eggs from this source. However, the Duckabush unit collected 2,870,000 eggs from the early run in Duckabush River and both stations secured from the late run in the Walcott slough field more than 8,000,000 eggs. The spawned-out adults were transferred to the Quilcene dehydrating plant, and the dry salmonmeal was utilized at a number of trout hatcheries for fish food. The Quilcene hatchery supplemented its salmon work by concentrating on the production of trout fingerlings during the summer months for the stocking of local waters. At this station a new building was constructed and the necessary troughs and equipment were installed

for conducting pathological studies.

#### MARINE SPECIES

The Boothbay Harbor (Maine) station collected 1,419,860,000 cod, 517,305,000 pollock, and 417,832,000 haddock eggs which, after being fertilized, were liberated upon the natural spawning grounds of the respective species. From 670,000,000 flounder eggs incubated in the hatchery, a hatch of 90 percent was attained. The number of eggs of this species handled was in excess of last season's by 76,000,000. In cooperation with the Sea and Shore Fisheries Commission of Maine, lobster culture was continued. Near the Bureau's hatchery this agency constructed a rearing station that is equipped with 500 lobster-rearing compartments. It is believed that when all details have been completed this unit will have facilities for rearing 1,000.000 lobsters to the fourth larval stage. There were on hand at the beginning of the year 327,400 lobster fry from which a number of fourthstage lobsters were raised and liberated at different points along the coast of Maine. During the spring of 1939, 3,915 adult egg-bearing lobsters were secured. Some of these adults were placed in cod boxes which had been rearranged in order that the young lobsters could hatch normally. Eggs were stripped from the others and placed in McDonald hatching jars for incubation. On June 30, there had been hatched 3,899,000 lobster fry, of which 1,045,000 were placed in the

rearing station, the remainder being liberated.

On September 21, 1938, the Woods Hole (Mass.) station was struck by a hurricane and tidal wave which destroyed windows, lattice work, slate shingles on the roofs, docks, sea wall, salt-water suction pipe line, and other property. The wooden portion of the east dock and sea wall was razed. Considerable time and funds will be required to rehabilitate this unit. The new suction line has been installed and other necessary repairs were made in order that the station could carry on its flounder work. Approximately 633,987,000 flounder eggs were collected and 568,530,000 fry were hatched and distributed. Approximately 50 percent of these fry were liberated in the coastal waters of Massachusetts—the remainder being planted along the coasts of New Jersey and Rhode Island, and in Long Island Sound and Narragansett Bay. Through the cooperation of the local commercial fishermen, there were collected 13,484,000 mackerel eggs from which 11,060,000 fry were hatched and liberated in Vineyard Sound and Buzzards Bay.

The fish-cultural activities at the Gloucester (Mass.) station consisted of the propagation of pollock, flounder, haddock, cod, and lob-There was a noticeable decrease in the production of the three former species, whereas there was a slight increase in the number of cod handled. Several spawn-takers were assigned to commercial fishing vessels for the purpose of collecting pollock, haddock, and cod eggs, a large percentage of which, after fertilization, were planted on the spawning grounds. The hatchery was also operated to capacity when eggs were obtainable. The total number of eggs collected was slightly in excess of 3½ billion. The lobster-cultural work was carried on in cooperation with the Massachusetts Department of Conservation, the same as last year. Four hundred and ten seed lobsters produced 3,221,600 eggs which were incubated in McDonald hatching Due to insufficient feeding equipment, it was necessary to liberate the greater percentage of the young lobsters in the third larval stage. Under the auspices of the P. W. A. and W. P. A., the buildings and equipment at this point were reconditioned and overhauled. Major changes consisted of the following: 15,000-gallon storage tank constructed, main hatchery building, storehouse and workshops reroofed, extension constructed on southwest side of boiler room to provide additional space for new boiler, new boiler installed as a replacement for the obsolete boiler, wharf repaired, new concrete floor poured in hatchery building, and all buildings given one coat of paint.

#### GREAT LAKES SPECIES

As Michigan maintains a closed season during the height of the spawning period for whitefish and lake trout, the collection of eggs of these species by the Duluth (Minn.) station was restricted to collecting fields in that section of Lake Superior not controlled by the State of Michigan. All lake trout and whitefish eggs obtained in Michigan waters were taken either before or after the closed season, and were of an inferior quality, with a resultant poor hatch. About 5,325,000 lake herring eggs were obtained from commercial fishermen from which

3,000,000 fry were liberated in Minnesota waters. The collecting of pike perch eggs was carried on in cooperation with the United States Forest Service. From 21,500,000 eggs of this species collected, 13,640,000 fry were distributed. Brook, rainbow, and brown trout eggs were hatched at this station for the stocking of local trout waters and for the Cascade rearing ponds in the Superior National Forest. The low temperature of the hatchery water supply induced high mortality among the trout eggs. Repairs and improvements were made to buildings and equipment by P. W. A. and W. P. A. workers.

Because of the high water temperatures which existed at the normal spawning period, the whitefish spawning season on Lake Erie in the vicinity of the Put in Bay (Ohio) hatchery was unusually late. However, more than 48,200,000 whitefish eggs were collected and placed in the hatchery. On December 29 the water-supply line to the hatchery froze, necessitating the planting of all eggs in the lake. There were 943,340,000 pike perch eggs collected from the 6 fields worked—one of the largest collections in the history of this station. The most productive field was at Port Clinton, where more than 500,000,000 eggs were secured. The propagation of both species was carried on in cooperation with the Ohio Conservation Division.

Due to the shortage of funds, the Cape Vincent (N. Y.) station was unable to send spawn-takers into the field. Therefore, it was necessary to depend upon the local commercial fishermen for the supply of lake trout and whitefish eggs. There were 1,108,800 lake trout eggs handled, while 70,000 whitefish eggs of poor quality were received. The major activities are the propagation of game fish, particularly smallmouth black bass, and the operation of substations for the rearing of trout. This phase of the work is discussed elsewhere in this report. At the Swanton (Vt.) substation all buildings were reroofed and painted, but there were no fish-cultural activities carried on. This unit has, in previous years, handled pike perch and vellow perch.

#### ANADROMOUS SPECIES. ATLANTIC COAST

The Edenton (N. C.) hatchery surpassed its 1938 collection of shad eggs by taking 11,134,000 from which 7,134,000 fry were hatched. All of these fry were planted in Albemarle Sound and its tributaries, with the exception of 500,000 which were planted in hatchery ponds for investigation and study. A culture of daphnia was maintained in the ponds until the shad were seen swimming along the shoreline, at which time artificial food was given them. The food consisted largely of ground fresh fish and shrimp meal. A new field was located on the other side of the sound near Mackeys, from which 8,300,000 white perch eggs were collected. A limited number of yellow-perch eggs were secured. The Edenton station propagates pondfish for the stocking of inland waters, supplementing its work with the commercial species. This unit was favored with W. P. A. and P. W. A. projects, which resulted in the completion of several ponds, a residence and other improvements. The Weldon (N. C.) substation was operated in cooperation with the Conservation Department of North Carolina for the hatching of striped bass, and 3,413,000 eggs of this species were collected.

The Orangeburg (S. C.) station operated an auxiliary hatchery on the Edisto River near Jacksonboro for the propagation of shad. There were 1,876,000 eggs collected, from which 1,534,000 fry were liberated in the Edisto and Ashepoo Rivers. While this number does not equal the records of previous seasons, it does represent an increase

of one-half million fry over last year.

At the Fort Belvoir (Va.) hatchery, located on the Potomac River, the main fish-cultural activities were the collecting and hatching of shad and yellow-perch eggs. The collection of shad eggs exceeded that of last season by more than 10 million, while there was a slight recession in the number of yellow-perch eggs secured. A one and one-half story, five-room, brick-veneer residence was constructed, and the marine railway and carriages were rebuilt.

#### GAME-FISH PROPAGATION

One would consider practically the entire output of the Bureau's hatcheries as coming within this category, since all species propagated, except lobster, whitefish, herring and shad, are at some time or

place sought by sportsmen.

Never in the history of the Bureau have the demands been so great for game fish. This may be ascribed in part to the large number of reservoirs constructed by the Department of Agriculture in its soil-conservation program, the impounding of large bodies of water by hydro-electric projects, the flooding of areas by the Bureau of Biological Survey to create migratory bird refugees, and to the prosecuting of stocking programs formulated by various Federal and State agencies. However, the innate popularity of angling among all classes is probably the most comprehensive explanation for the demand.

The following data cover the activities of the stations handling the families Centrarchidae and Cichlidae and the species of the Salmonidae

found largely in inland waters.

#### ROCKY MOUNTAIN TERRITORY

Due to adverse weather during the spawning season, and water shortage throughout the summer, the output of pondfish from the Dexter (N. Mex.) station was below normal. Approximately 121,000 of the fish distributed ranged from 5 inches in length to legal size. In cooperation with the New Mexico Department of Game and Fish, a stocking program was formulated for the waters of that State. This program was adhered to as much as possible, although a portion of Dexter's production was utilized for the stocking of Arizona, Colorado, and Texas waters. Heretofore, predatory birds have devoured large numbers of this unit's brood stock each winter and a network of wires was attached to cables over some of the ponds in order to frighten such visitors. A concrete cistern of 30,000 gallons capacity, for storing water for domestic use, was constructed. The metal fish tanks were removed from the holding house and replaced with 14 concrete tanks. All station buildings were repaired and painted and a large cactus garden was planted near the entrance to the station.

The output of fish from the Santa Rosa (N. Mex.) substation was practically the same as that of the previous season. A number of choice smallmouth black bass fingerlings were saved out of last year's hatch, and it is anticipated that the 1940 output of this species will be greatly increased. The number of food organisms produced in the ponds appeared to justify the expense involved in fertilizing them

with a mixture of sheep manure, superphosphate, and cottonseed This unit's pond system was increased by 6 ponds during

the vear.

At the Elephant Butte (N. Mex.) station all buildings and ponds were completed by the Reclamation Service and placed in operation. From 13.4 acres of water more than 1/2 million fingerling pondfish were produced, of which 373,750 were largemouth black bass. stock of crappie, which are reported to have reached a size of 3 pounds in the warmer waters of the Pecos Valley watershed, was secured for the purpose of introducing a large-size strain of this species into the waters of the Rio Grande.

In the Utah field the Springville station distributed 1% million fingerling fish and shipped 980,000 trout eggs to other hatcheries. The production of largemouth black bass was negligible. Experiments were conducted to determine the effect of diet upon the fertility of rainbow trout eggs. The old wood-pipe hatchery-water supply line was replaced with a 10-inch asbestos-wrapped 12-gage spiral-

welded steel line.

At the Bear Lake (Utah) substation 5 species of trout and chum salmon were handled. This unit collected 1,174,000 eggs from local trap sites and received 657,820 eggs from other stations. In addition to the construction of a new residence, all buildings were painted by W. P. A. and P. W. A. employees.

All buildings and ponds were completed at the Las Vegas (Nev.) unit. During the early spring this station secured an ample stock of brood fish from which 80,000 fingerling black bass were planted

in Lake Mead prior to the close of the year.

On September 11, 1938, the Bureau took charge of the Clark Fork (Idaho) hatchery, which was constructed as a W. P. A. project sponsored by the Idaho Fish and Game Department on land donated by the Bonner County Sportsmen's Association. Gratifying results were obtained from the eggs handled and it was possible to liberate more than 1/2 million fingerling silver and blackspotted trout during

the latter part of the year.

In the Colorado territory the Leadville station continued to cooperate with local parties in the collecting of trout eggs. The Bureau received several million eggs from such sources at a nominal cost, thereby eliminating the necessity of maintaining a brood stock at Several thousand trout were transferred to the Crystal Lake Nursery to be reared to a larger size before liberation. There were 4,300,000 rainbow eggs collected from Eagle Nest Lake during April and the early part of May. More than 1 million of these eggs were assigned to the New Mexico Department of Game and Fish for hatching and subsequent planting in the waters of the northern part of the State. The hatchery building and 2 cottages at Leadville were reroofed and a two-car garage was built. A new cottage was constructed at Turquoise Lake from lumber milled by W. P. A. labor.

An average production of fingerling trout was obtained at the Creede (Colo.) substation. Due to the scarcity of spawners, the collection of brook and rainbow trout eggs from Lake San Cristobal was materially below that of 1938. However, the eggs obtained were of very high quality, eyeing up to 98 and 99 percent respectively. Three old concrete ponds were dismantled and 4 new concrete ponds were constructed in the same area. A two-car garage was built and

the river bank in front of the hatchery building was riprapped with rock.

In the Idaho field the number of eggs taken from the brood stock at the Hagerman station was disappointing, due to the large number of barren females. The reason for this large percentage of barren females is not definitely known, but it is ascribed to diet. Experiments are being conducted to ascertain if this assumption is correct. Approximately 1 million large fingerling trout were produced. The rearing-pond system was greatly increased during the year by W. P. A. and P. W. A. employees.

The substation at Salmon, Idaho, which heretofore had been operated on a seasonal basis, was operated during the entire year in cooperation with the Idaho Fish and Game Department primarily for handling the rainbow eggs collected at Williams Lake and other local waters. Extensive repairs and improvements, including the rearranging of the hatching and rearing equipment in the hatchery, were made

during the winter.

The distribution of rainbow trout from the Bozeman (Mont.) station was somewhat limited, due to the high mortality among this species during the latter part of the previous year. Normal success was attained with the other species of trout and grayling handled. Elk carcasses received from Yellowstone Park were utilized for fish food. This station was the beneficiary of P. W. A., W. P. A., and N. Y. A. projects which made possible extensive repairs and improve-

ments to buildings, grounds, and equipment.

The Glacier Park (Mont.) substation received 2,501,480 blackspotted trout and 400,000 rainbow trout eggs from the Yellowstone Park unit and planted the resultant fish in the advanced fry stage in The water-temperature range is too great for successful Park waters. hatchery operation at this point. In view of this and the need for a new and improved hatchery for producing larger fish for the stocking of waters of the Glacier National Park, an alternative site was located 2 miles west of Creston. This unit, as planned, will consist of a 48-trough hatchery building of frame construction, containing an office, laboratory, 2 lavatories, and a storage room. There will be 12 concrete raceway ponds, each 107 by 10 feet; 10 Foster-Lucas concrete ponds of oval shape, each 56 by 13½ feet; 1 utility building and several residences. The grounds are to be landscaped and provision will be made for a picnic area which will be supervised by the Park Service. The construction of this hatchery was started on March 1, 1939, under the auspices of the W. P. A., P. W. A., and N. P. S., with the Bureau furnishing technical advice. Due to adverse weather conditions and unforeseen constructional difficulties the work is somewhat behind schedule, but it is anticipated that this station will be ready for operation in the spring of 1940.

The production of the Ennis (Mont.) substation was largely utilized in the restocking of waters of the Madison Valley watershed in an effort to reestablish the excellent sport fishing of the past years. The scarcity of adult rainbow and Loch Leven trout ascending the Madison River during the spawning season was more acute than ever. Consequently, this station had to rely on other sources for practically all of the eggs of these species. The major construction activities were erection of a four-room cottage, the extension of the water-supply main, installation of a hydroelectric turbine and generator unit, the

installation of a steam-heating plant in the hatchery building, and the

fencing of station grounds.

Although the bass production was small, the total output of the 4 species of fingerling fish handled at the Miles City (Mont.) substation was larger than during either of the 2 preceding years. production was attributed to an inadequate supply of mature brood fish and the delay in harvesting, which was caused by very hot weather prevailing after a large amount of the water had been drawn from the large lake. However, the large size of the fingerling bass collected compensated for the small number taken. The large number of reservoirs built by the Farm Security Administration in this section of the country is creating a bigger demand for pondfishes, especially catfish, and special effort is being made to increase the production of this species. From the Nebraska Conservation Commission 1,900 adults, 10,000 fry, and 40,000 channel catfish eggs, green and eyed, were received in exchange for grayling eggs.

Inasmuch as the work at the Yellowstone Park station covered the midsummer months extending into parts of 2 fiscal years, the data furnished here cover the season of 1938. Because of high-water conditions, much difficulty was experienced in maintaining the fish For instance, the trap in Pelican Creek, which was by far the largest producing trap in 1937, could not be operated from May 25 to June 10 because of extremely high water. Notwithstanding these conditions, the take of eggs was more than 37 million, which is considered an average collection although it was approximately 10 million less than during the season of 1937. There was an increase in the number of fish reported as being taken from the waters of the Yellowstone Park this year, while the number of Park visitors was slightly less than last year. In 1938 there were 163,859 fish reported at the checking stations, while the number reported in 1937 was

135,654. The Jackson Hole (Wyo.) substation, which was operated on a seasonal basis, produced approximately 870,000 blackspotted, lake, rainbow, and brook trout, and grayling for stocking waters of the Grand Teton National Park and the Teton National Forest. A C. C. C. project permitted development of a number of improvements, including the repairing of 4 circular concrete ponds, the construction of 2 rectangular ponds, and the landscaping of station grounds.

A new three-stall garage was constructed and all buildings were painted at the Saratoga (Wyo.) station. The pond system was enlarged by the construction of 2 concrete ponds 100 by 10 feet, 2 concrete ponds 60 by 6 feet, and one dirt pond with concrete ends. Fishcultural work was carried on along usual lines and normal success was attained in the production and distribution of trout fingerlings.

The Baker Lake (Wash.) station, which was formerly used for the propagation of salmon, was remodeled for the purpose of rearing trout to stock Baker Lake and tributary waters. During the early part of the year C. C. C. enrollees from a local camp assisted in the laying of pipe lines, rebuilding the intake dam, etc. This unit was operated on a fish-cultural basis only from June 1 to June 30. The fish which were received by transfer from other stations are being reared to a larger size before planting. Consequently, no distribution was made from this hatchery during the fiscal year.

From the 12 circular rearing ponds operated at the Spokane, (Wash.) substation, approximately 230,000 large fingerling brook, rainbow, and blackspotted trout were distributed. All except 6,000 of these fish were planted by the Conservation Departments of Washington and Idaho. A four-room, frame, one-story cottage, with concrete basement, was constructed. A concrete foundation for a hatchery building 38 by 54 feet was poured and fill made within the foundation walls preparatory to the laying of a concrete floor. At present, this station utilizes trough space in the local State hatchery for incubating its

trout eggs.

As there was no stock of eggs or fish on hand at the Mount Rainier (Wash.) substation at the beginning of the year, the entire unit, including water-supply lines, ponds, troughs, feeding tanks, and all fish-cultural tools and appliances, was thoroughly sterilized with calcium hypochlorite to eradicate fish parasites and diseases which had prevailed. When the shipments of eggs were received, they were sterilized by submerging them in a 1:2,000 solution of acriflavine for 20 minutes before they were placed in the hatching troughs. As a result of this precaution, the stock of fish at this hatchery remained free of all diseases during the year. This station collected rainbow trout eggs from Mowich Lake and received approximately 850,000 eggs of rainbow, brook, and blackspotted trout from other points. The greater percentage of the resultant fish were planted in the waters of the Mount Rainier National Park and the Snoqualmie National Forest.

The Spearfish (S. Dak.) station installed 4-foot red and green Neon lights under the surface of the water in some of the trout ponds to attract insects for fish food. One cottage was constructed and many repairs and improvements were made to the buildings, equipment, ponds, and water-supply system. The egg-take from the station brood stock was only about 50 percent of that of the past season, due to the large number of barren females among the rainbows and the heavy mortality of the Loch Leven stock prior to the spawning season. The small laboratory continued to be a very important unit at this station. Through weekly microscopic examination of all lots of fish many diseases are diagnosed and checked before they cause serious

trouble.

### NEW ENGLAND TROUT STATIONS

Owing to the appearance of furunculosis the latter part of last year, and the consequent disposition and destruction of all fish on hand, fish-cultural operations at the National Forest (N. H.) station were suspended until the receipt of eggs during the fall of 1938. The States of Vermont and New Hampshire furnished 1 million brook trout eggs with the understanding that the Bureau would provide food equal to their value. To supplement these eggs, approximately 1½ million were collected from yearling and 2-year-old fish held in the Whitefield rearing ponds of the New Hampshire Fish and Game Department. Repairs and improvements were prosecuted by W. P. A. and P. W. A. workers. The pond system was enlarged by the construction of additional raceways 3 feet wide by 165 feet long, in three equal sections with falls between. These ponds are arranged in such a way that four different water supplies may be utilized if necessary.

The hurricane which raged through the New England States on September 21 did little damage to the St. Johnsbury (Vt.) station other than blowing down some of the trees in the pine plantation. With the assistance of the W. P. A. and P. W. A. much valuable work was accomplished, not only in repairs to ponds, buildings, drainage lines, water supply, etc., but by the addition of several new raceways. A concrete intake dam in Sleepers River was constructed to replace an obsolete plank structure, thereby assuring a constant water supply at all times. As usual, the major fish-cultural activity was the hatching of approximately 1½ million brook trout eggs. At the beginning of the year the entire stock of brown trout and landlocked salmon fingerlings was wiped out by the parasite ichthyophthirius multifilis. The fish-cultural work of this station is carried on in cooperation with the Fish and Game Service of Vermont.

The Pittsford (Vt.) station continued its experiments in selective breeding of trout and conducted various other investigations. This year the adults yielded eggs at the rate of 1,424 per pound of fish. As the average fish-culturist recognizes 1,000 eggs per pound of trout as the normal production, the effect of selective breeding is obvious. This station was favored with W. P. A. and P. W. A. projects for the repairing and improving of buildings, equipment, and roadways.

The Craig Brook (Maine) hatchery collected 4,300,000 brook trout eggs, of which number approximately 2½ million were shipped to other Bureau stations. Shipments of rainbow and lake trout eggs were received, from which several thousand fingerlings were distributed. In accordance with an agreement between the National Park Service and the Bureau, the Acadia National Park was allotted 185,000 large fingerling brook trout for the stocking of waters under its control. Repairs and improvements were made to buildings, ponds, drainage and supply lines, roadways, etc., by P. W. A. and W. P. A. workers.

In order to facilitate the repairing of old ponds and enlarging the pond system, the Hartsville (Mass.) hatchery disposed of its brood stock of trout. Consequently no eggs were taken at this point. Approximately 400,000 brook and 27,000 rainbow trout fingerlings, ranging in size from 1½ to 4½ inches, were distributed. In cooperation with the State of Connecticut, 773,000 smallmouth black bass fry were collected from Wangum Lake; one-half of which were assigned to the State of Connecticut.

As the Nashua (N. H.) station was struck by a hurricane in September, a large amount of time has been spent by the personnel in rehabilitating it. In addition to this work, a garage and 4 concrete ponds were constructed. This unit suffered high losses among all species of fingerling and yearling trout the latter part of the year.

### COMBINATION TROUT AND PONDFISH STATIONS

Although most of the establishments in this category have heretofore been primarily concerned with the propagation of trout, several of them have enlarged their facilities for the propagation of warm-water species. In some cases the production of spiny-rayed fishes is almost equal to the output of some of the smaller units which are exclusively engaged in the handling of pondfishes.

At the Lamar (Pa.) station the hatchery building was completed during October and the necessary equipment placed therein, enabling

this unit to incubate trout eggs. More than 1 million brook, brown, and rainbow eggs were hatched. In addition to the furnishing of fish for rearing at the Ogletown substation, several thousand trout were allotted to conservation clubs to stock their nursery ponds. Nine ponds, ranging in size from ½ to 2 acres in area, for the propagation of warm-water fishes, were completed in time to be stocked with brood fish during the spring. C. C. C. enrollees assisted in the above construction work as well as in the landscaping of grounds and the

building of roads.

The Northville (Mich.) station's combined output of trout and pondfishes was in excess of one million. Approximately 660,000 trout were delivered to 5 cooperative feeding stations, 2 of which are within the boundaries of National Forests. Several thousand trout were consigned to the conservation departments of Indiana and Ohio for the stocking of suitable waters in their respective States. New outlet kettles were constructed in the 9 warm-water fishponds, and the ponds were graded. The hatchery water supply was materially increased by the construction of a concrete retaining wall across the southwest side of the spring pond. After repairs and alterations were made to all station buildings, they were painted.

The Powder Mill Park (N. Y.) hatchery, which is operated in cooperation with the Monroe County Park officials, reared several thousand trout to legal size before releasing them. This station also handled smallmouth and largemouth black bass for the stocking of

Monroe County waters.

The 65,000 trout liberated by the Carpenter's Brook (N.Y.) station, which is operated in cooperation with Onondaga County sportsmen, were all 5 to 7 inches in length. At the close of the year this unit was feeding more than 200,000 fingerling and yearling brook, rainbow, brown, and lake trout. No output of smallmouth black bass was recorded, as the ponds to be utilized for this species were not completed until during the fall months. Brood stock of this species was collected

and placed in the ponds this spring.

The Manchester (Iowa) station collected 2,992,000 rainbow trout eggs of which 89 percent were eyed. All of these eggs, with the exception of approximately 200,000, were shipped to other Bureau and State hatcheries. The production of smallmouth black bass was negligible, which was ascribed to the stocking of the rearing ponds with forage minnows previous to the introduction of bass fry. A new dwelling was constructed and residence No. 3 was moved to a new location and provided with a basement. Two 25-foot circular concrete ponds were built and a new main-supply pipe line was laid from the spring to the hatchery.

In an effort to step up the production of warm-water fish at the Flintville (Tenn.) station, 5 new ponds were excavated. Four of these are approximately 1 acre in area, the other being 2 acres. This brings the number of ponds up to 16, with a total area of 17¼ acres. The reservoir from which these ponds receive their water supply was enlarged. From 250,000 eyed rainbow eggs received by transfer, sufficient fish were produced to meet the requirements for this species

in that territory.

The most outstanding feature of the fish-cultural work at the Erwin (Tenn.) unit was the production of more than 1,000,000 pondfish. The output of trout was on a level with that of last year. A new residence was constructed and the pond system enlarged.

Although the total number of rainbow trout eggs collected at the Neosho (Mo.) station was approximately 570,000 less than last year, the number shipped, due to the superior vitality of the eggs, nearly equaled that of last season. The selected brood stock of rainbow trout produced 1,305 eggs per pound of fish. Due to favorable weather during the pondfish spawning season, the output of warmwater species was the largest in the history of the station. Two rectangular trout ponds east of the hatchery building were razed and replaced by 3 circular concrete ponds. A concrete roadway was built and considerable landscaping was accomplished by W. P. A. laborers.

At the Bourbon (Mo.) substation, which is operated on a cooperative basis for the sole purpose of producing rainbow trout eggs, there

was a material increase in the yield.

The collection of rainbow trout eggs from the Wytheville (Va.) station's brood stock amounted to 2,152,000 green eggs, which was slightly less than the previous season when 2,237,000 were collected. Approximately 1,133,000 of these eggs were shipped to other Federal and State hatcheries. The production of brook trout was the lowest in recent years, due to a gill infection which practically wiped out this species. The smallmouth black bass yield was also negligible, due to sudden changes in the temperature during the spawning season. The output of bream and rock bass was normal. The fry resulting from the pike perch eggs received from the Put in Bay (Ohio) unit were liberated in New River. Both hatchery buildings were reroofed and approximately 3,000 feet of pipe were laid to the ponds which are utilized for propagating spiny-rayed fishes. A new six-car garage was constructed, and eight brood trout ponds were rebuilt.

The inferior quality of the rainbow and Loch Leven trout eggs collected at the White Sulphur Springs (W. Va.) hatchery was ascribed to the food fed the brood stock. Due to the rebuilding of ponds utilized for the propagation of warm-water fishes, the output of bass was insufficient to meet the demands in that locality. The painting of all buildings except the work shop was completed. A number of new troughs were constructed and installed in the hatchery building. At the close of the year the spring pond and supply ditch were being walled up with stone, and the surrounding grounds landscaped.

At the Leetown (W. Va.) station results in trout-cultural work this year were gratifying, both as to the size and numbers of fish produced. A total of 625,735 fingerling brook, brown, and rainbow trout, of which number approximately 70,000 were in excess of 5 inches in length, were distributed. However, the percentage of hatch obtained from the 3,244,000 trout eggs collected from the station's brood stock was very low. Several thousand trout were assigned to the Monongahela and George Washington National Forests for the stocking of waters within their boundaries. Experiments in the feeding of fish meal, cod liver oil, and kelp meal to trout were carried on in order to further test their value as fish food. Other experiments were made to determine the effects of over- and underfeeding of trout. duction of spiny-rayed fishes was quadruple that of last season. experiments in the stocking of warm-water rearing ponds with blackhead minnows were continued for the purpose of determining how many forage minnows should be stocked per acre of water, and the time of year that they should be introduced into the rearing ponds. Three new residences were completed, and a sewerage system, which is for the combined use of the residences and the new dormitory, was put into operation. Eleven ponds, 500 feet long by 50 feet wide, and a series of 15 small ponds, none of which was in excess of 150 feet in length, were excavated and part of them were placed in operation. A new 11-car garage with an oil-drain pit was built and a cold-storage room with a quick freeze compartment was constructed as an addition to the old garage building. In addition to the above construction work, pond outlet kettles were poured, drainage and supply lines were laid, old buildings were repaired and painted, and considerable land-scaping was accomplished.

The output of trout from the Cape Vincent (N. Y.) station and its auxiliaries at Cortland, Watertown, and Barneveld was in excess of 1,500,000. Although the production of smallmouth black bass at Cape Vincent was 92,000, this number was inadequate to meet the demands in that locality. In order to increase the output of this species, additional ponds are being constructed. At the close of the year four were nearing completion and one other was partly excavated. At the Cortland unit the circular pools were completed and

both hatchery buildings were enlarged.

The Lake Mills (Wis.) station established an all-time record in the production of pondfishes; largemouth black bass being the major species handled. The output of trout was normal, approximately 232,000 fingerling brook, brown, and rainbows being distributed for the restocking of waters in that vicinity. During the year, ponds were excavated as follows: 2 ponds 4 acres in area; 1 pond 1 acre in area; and 5 ponds ranging from ½ to ½ of an acre. Outlet kettles and the necessary supply and drainage lines were installed in these ponds. The exteriors of all buildings were given 2 coats of paint and the interior of the hatchery building was painted.

### APPALACHIAN AND BLUE RIDGE TROUT STATIONS

The Smokemont (N. C.) station produced 326,000 rainbow and brook trout, ranging in size from 3 to 7 inches, for the stocking of waters in the Great Smoky Mountain National Park and the Cherokee Indian Reservation. A built-in refrigerator for the storage of fish food was constructed and the necessary refrigerating machinery installed.

The Pisgah Forest (N. C.) unit, which is located on the Davidson River in the Pisgah National Forest, reared its output of approximately 50,000 brook, brown, and rainbow trout to a large size before releasing them. Fishing records maintained for the season would indicate that better catches are now being made from the waters of the Pisgah Forest. This is attributed to the stocking and stream

management programs formulated.

The Walhalla (S. C.) station conducted its fish-cultural activities along routine lines and attained normal success in the production and distribution of brook and rainbow trout fingerlings. A hydroelectric unit was installed to provide power and lights for station operations. The trout reared in the ponds at the Franklin (N. C.) and Clayton (Ga.) substations were liberated in the waters of the Nantahala and Chattahoochee Forests, respectively.

#### PONDFISH STATIONS

Although records indicate that there has been a larger number of pondfish distributed in previous years, a large percentage of such fish were obtained from rescue operations along the Mississippi River. The actual number of warm-water fish produced at the various hatcheries sets an all-time record. The largest increase was in the production of largemouth black bass. Notwithstanding the fact that weather and other conditions, over which there is no control, influence the production of pondfish, the principal requirement for a large output of bass and other warm-water species is space. Therefore, in an endeavor to properly stock waters which are suitable for such species, the Bureau is constructing new hatcheries, and pond acreage at the old-established units is being enlarged as funds will permit.

The total production of largemouth black bass, sunfish, and crappie at the Harrison Lake hatchery, located at Roxbury, Va., was practically the same as last year. Efforts are being made to increase the natural food by introducing aquatic plants in the ponds. Pond dikes were straightened, raised, and regraded, and grounds were

landscaped by enrollees of a nearby C. C. C. camp.

For some unknown reason the production of each species, forage as well as game, handled at the Lake Park (Ga.) station was far below normal. As the vitality of the fish collected was low, there was high mortality in the holding shed and on some of the distribution trips. The Division of Wildlife of the State of Georgia distributed the larger portion of the fish produced at this unit, as well as those produced at the Warm Springs (Ga.) station. During the year the following four new buildings were constructed at Lake Park: Residence, two-car garage, holding shed, and a small office building.

Roads were repaired, and two new bridges were constructed.

As the Louisville (Ky.) station was inundated in 1937, and practically all of the brood stock was lost, this hatchery's annual output is not, as yet, on a level with that for the years previous to the flood. The wild-brood stock collected from various sources is becoming acclimated and domesticated to pond conditions, and, with favorable weather conditions during the spawning season, the output of bass fry should have been greater. In addition to the propagation of smallmouth black bass, largemouth black bass, sunfish, crappie, and rock bass, this unit raised golden shiners and blackhead minnows for forage. A three-car garage and carpenter shop was constructed, and all buildings were repaired and painted. Two new ponds are being excavated. At the close of the year one pond was completed, except for the outlet kettle. The construction activities were carried on under the auspices of W. P. A. and P. W. A.

The Tennessee Valley Authority's hatchery at Norris, Tenn., which is operated by the Bureau, liberated its production of bass and bream in Norris Lake. From the 500,000 pike perch eggs furnished this unit from the Put in Bay (Ohio) station, 450,000 fry were hatched

and planted in the lake.

From the Palestine (W. Va.) hatchery, which was operated in cooperation with the West Virginia Conservation Commission, 181,510 fingerling bass, bream, and crappie were distributed. This station was successful in securing a brood stock of channel catfish.

At the Orangeburg (S. C.) hatchery, and its nearby auxiliaries, the production of 1,009,185 fingerling pondfish exceeds that of any previous year. This output is a 94-percent increase over that of last season. Largemouth black bass and bluegill sunfish were the major species handled, while a limited production of redbreasted sunfish, red-eared sunfish, warmouth bass, catfish, crappie, and yellow perch was attained. The completion of a 900-foot section of the reinforced-concrete storm channel provides a canal the entire length of the pond system, thus eliminating hazards which greatly endangered the station ponds heretofore. A new one-story residence, consisting of six rooms and bath, was constructed. A storage shed and two garages were also constructed. The painting of all buildings was about 90 percent completed at the close of the year.

From 25 acres of water available for the production of fish at the Hoffman (N. C.) unit, 843,115 fish, of which all except 25,000 were fingerlings, were distributed. This output consisted of largemouth black bass, warmouth bass, sunfish, and crappie. In accordance with an agreement, several thousand of these fish were liberated in the ponds and lakes on the land utilization project in which this station is located. A site was cleared for the construction of 3 additional ponds, each of approximately 1 acre in area. One of the ponds was completed and considerable excavation work was done on the others. A combination holding and shipping shed, housing 4 concrete holding

tanks, was constructed.

The output of fish from the Marion (Ala.) hatchery was the largest in the history of the station. The total output of largemouth black bass, bream, crappie, and rock bass was 3,228,390. Although some of the early bass eggs were lost on account of adverse weather conditions, the production of this species was in excess of 1,067,000 for the year. This station was unable to maintain a sufficient stock of crappie and rock bass and, consequently, the output of these species was inadequate to meet the demand. Twelve ponds, covering 16 acres, were added to the pond system. A well was drilled which produced 120 gallons of water per minute to furnish the necessary water for these ponds. A new holding shed is being constructed near this well in order to facilitate the handling of fish produced in the surrounding ponds. The levees on several of the old ponds were reinforced with dirt obtained from shallow areas. In addition to the above construction work, a number of repairs and improvements were made to buildings, roads, fences, drains, pond levees, etc.

Although the Cohutta (Ga.) station was under construction during the entire year, a limited production of smallmouth black bass, largemouth black bass, and Kentucky bass fry and small fingerlings was obtained for distribution during the spring. Six ponds were excavated during the period, which gives this station a total of 12 ponds. The office building, garage and workshop, holding house, residence, and pumphouse were completed. Grounds were cleared of underbrush and dead trees, and the areas around the buildings and pond embank-

ments were sodded.

In spite of the fact that high winds prevailed at the Lyman (Miss.) station during the spring spawning season, this unit produced approximately 684,000 fingerling black bass and bream. The bass at this station grow very rapidly during the early part of the season, some attaining a length of 4 inches in 6 to 8 weeks. Owing to the various

sizes of bream taken from the ponds when they were drained, it is believed that this species spawned at least 9 months of the year in this By enlarging the existing ponds, the water acreage was increased approximately 81/2 acres. All levees were regraded and seeded with Bermuda grass, and willows were planted to prevent erosion around embankments except where there was danger of the roots

clogging drainage lines.

Seventeen ponds covering 11.83 acres at the Marianna, (Fla.) unit were completed during the fall of 1938. On filling these ponds with water it was found that 6, due to seepage through the bottoms, would not hold sufficient water for the production of fish. Therefore, the output of 114,000 fry and 92,650 fingerling bass distributed from this station during the spring represents the production obtained from 5.93 acres of water. Difficulty was also encountered in obtaining sufficient brood stock from local sources for properly stocking the ponds that were utilized. As there was an unusually heavy culture of daphnia in the ponds used, the fish showed a remarkable growth. At the close of the year preparations were being made to apply a waterproofing treatment to the bottoms of all ponds. All buildings were completed and the surrounding grounds landscaped.

The Tupelo (Miss.) station, which has a pond area of only 161/2 acres, produced more than 850,000 bass and bream, of which all except 198,000 were fingerlings. While the output of fingerling bass per acre was 42,500, the bream production was below 17,000. A six-room cottage was constructed. Approximately 8 inches of dirt was removed from four of the pond bottoms to eliminate the growth of water lilies, which have hindered the production and collection of young fish.

Inasmuch as several of the ponds at the Warm Springs (Ga.) station were not in operation, because of the fact that new supply and drainage lines were being laid and pond banks were being repaired and widened, the output of fish was slightly less than that of last year. Nevertheless, this unit produced approximately one-half million bass and bream for distribution. Catfish were received from the Lake Park unit and redistributed to applicants. In addition to the above con-

struction activities, all buildings were repaired and painted.

Although unfavorable weather conditions prevailed and the water in the ponds was turbid during the spawning season, the Mammoth Spring (Ark.) unit attained a new record in the production of smallmouth black bass, with an output of 237,000 fry and 150,000 fingerlings. In addition to this species, largemouth black bass, rock bass, and bluegill sunfish were handled. A five-room cottage was constructed and repairs were made to all buildings, the barn being converted into a two-car garage. New concrete kettles were poured in three ponds and the levees and bottoms to all ponds were repaired and graded.

The city of St. Louis, Mo., with the assistance of the W. P. A. and P. W. A., built at the Forest Park station a new stone structure consisting of living quarters, office, garage, workshop, and holding shed. Ten new lakes were built and several of the old lakes and lagoons were deepened, cleaned, and reconditioned. New outlets were constructed and a better water supply system arranged to each lake and lagoon section. Due to these activities some of the lakes were not on a productive basis. Nevertheless, this unit produced approximately

400,000 fingerling fish for distribution. This station has proved a very valuable addition to the Bureau, inasmuch as it furnishes fish for the stocking of waters which heretofore had to be supplied from

some remote point.

At the Tishomingo (Okla.) station approximately 14 acres of additional ponds were constructed. The following stone structures were built at this point: Four-room residence, three-stall garage, tool shed, and oil house. A holding shed is also under construction. Shortage of rainfall lowered Pennington Creek, the source of water supply, to where it was not flowing enough to maintain the proper level in the ponds. However, the 1939 output of fish was 716,980 fingerlings. Efforts to propagate channel catfish were a failure.

At the Natchitoches (La.) station W. P. A. and P. W. A. workers were engaged throughout the greater part of the year in the excavating of new ponds, laying of drainage and supply lines, building of a fence, gravelling of roads, repairing old pond bottoms and embankments, and constructing outlet kettles. Nevertheless, the output of fingerling largemouth black bass, warmouth bass, and sunfish was in excess of

the previous year's record.

In addition to distributing more than 1 million fingerling largemouth black bass, bluegill sunfish, Rio Grande perch, and channel catfish, the Uvalde (Tex.) station liberated approximately 400,000 bass fry in local waters. The 39 ponds, totalling 44 acres in area, were devoted to the propagation of game species of fish, and 12 ponds, about % acre each in area, for the handling of forage minnows. As the water at this hatchery contains certain chemicals, the steel water-supply lines were corroded to the point where it was necessary to replace them. At the end of the year approximately 85 percent of the lines had been replaced with composition pipe. An addition to the implement building was constructed and the exteriors of all station buildings were painted.

The output of fry and fingerlings from the San Marcos (Tex.) unit approximated normal figures. Several old buildings were razed and a new combination garage, shop, and storage structure was built. A small building was also constructed for the purpose of storing paint, oil and grease, and other highly inflammable supplies. All old station buildings were repaired and painted. Considerable work was

done on ponds, grounds, levees, and roads.

From the brood stock of 4 species of fish handled at the San Angelo (Tex.) Station, more than ¼ million fingerling fish were distributed. Extensive daphnia culture was carried on during the spring months to produce food for the fry, and golden shiners were introduced in the rearing ponds when the bass were about 1½ inches long. A residence and double garage were constructed during the year. The pond system drainage line was completed. The exteriors of all buildings were painted, the grounds around the new buildings landscaped, and the station driveways were regraded.

At the Fort Worth (Tex.) station the output of sunfish and warmouth bass was in excess of that of last year, while there was a slight recession in the number of largemouth black bass, crappie, and catfish distributed. This station was enlarged by the acquisition of a site containing 31 acres, on which 10 ponds, covering approximately 14 acres, were excavated. All old pond embankments were repaired

and the bottoms of 2 were regraded. New concrete outlet kettles were built in all ponds. The following buildings were constructed: Four-room cottage, garage and store building, oil and paint house, blacksmith shop, and holding shed. In addition to these activities the station property was fenced in, all buildings were painted, the drainage system was enlarged, roads were graded, and grounds were

landscaped.

The Welaka (Fla.) station, which was received by transfer from the Farm Security Administration the latter part of last year, was favored with W. P. A. and P. W. A. projects for prosecuting extensive construction work. Complete individual supply and drainage systems were installed in eight ponds at the Beecher unit. New kettles were constructed in eight new 2-acre ponds, and pond bottoms were graded to allow sufficient drainage for collection of fish. There was installed a new supply and drainage system for the series of 24 one-acre ponds. Repairs were made to old residences. A four-car garage was constructed, a laboratory building was erected, and two 6-room stucco cottages were partially finished. Nevertheless, this unit distributed approximately 100,000 fry and 300,000 fingerling black bass as well as a limited number of sunfish.

At the Fairport (Iowa) station considerable repair work to pond bottoms, embankments, kettles, and supply and drainage lines was accomplished. For reasons previously mentioned, salvage work in this field was not necessary this year. As this unit is fully equipped to handle rescue work, it cooperated with the State Conservation Department and sportsmen's organizations in eastern Iowa in the collecting of fish from stagnant inland waters and liberated them in suitable waters. Gratifying success was attained in the culture of

vellow and channel catfish.

In the Indiana field, the Rochester station established an all-time record in the production of pondfishes. The total output of all species handled at Rochester and the Argos auxiliary was in excess of 2 million—an increase of more than 1 million over last year. Further experiments in the culture of spoonbill catfish in ponds were undertaken at this hatchery, but the results were nil. The dam at Lake Manitou, the station's water supply, was torn out and rebuilt. Sheet steel piling was driven along the toe of the dam to a depth of 18 feet to prevent seepage, and the floor, wing walls, and apron were reconstructed of reinforced concrete. A six-room residence and garage, both of brick, were constructed. A new bridge was built across the creek that traverses the station grounds.

### UPPER MISSISSIPPI WILDLIFE AND FISH REFUGE

Up to this year the principal activities within the Upper Mississippi Wild Life and Fish Refuge have been the salvage of stranded fish in overflow areas. However, the virtual completion of the 9-foot channel has nullified this activity, as is shown by the fact that only 1,864,820 fish were rescued in comparison with the annual turnover of 40 or 50 million fish in previous years.

A new phase of activity has, therefore, been undertaken by the construction of an extensive series of propagating ponds, many entirely artificial while others are seminatural. Several of these have

been in use for the past few seasons and have yielded excellent results. During the year additional pond acreage was under development at Genoa, Wis., and Guttenberg, Iowa. The former, which produced approximately two million bass fingerlings, now constitutes an extensive fish-cultural unit, while the latter, when completed, will be one of the largest hatchery developments in the country. A number of years will be required for full realization of this program, but the projects are being placed in productive operation as fast as individual ponds can be completed. The La Crosse (Wis.) Station, headquarters for these activities, has hatched and distributed 1,082,600 trout for direct planting in suitable waters and for transfer to Forest Service rearing ponds and cooperative nurseries maintained by sportsmen's clubs.

The Homer (Minn.) substation was largely engaged in the overhauling and repairing of equipment, boats, trucks, etc., utilized in that territory. The personnel also constructed seines, dip nets, egg cases, boats, outlet kettle forms, and other apparatus for use at the various hatcheries.

Fish rescued and restored to original waters, fiscal year 1939

Species	Number
Black bass	9, 700
Crappie	
Sunfish	210, 400
Catfish.	1, 379, 000
Yellow perch	
Pike pickerel	2, 620
Buffalofish	
White bass	
Miscellaneous	9, 000
١ .	<del></del>
Total	1, 864, 820

Note.—The station at Guttenberg, Iowa, handled 1,352,020 of the above-enumerated fish and the station at Marquette, Iowa, handled 512,800.

#### AQUARIUM

The Bureau of Fisheries' aquarium, which is located in the basement under the main lobby in the Department of Commerce Building, has constantly increased in popularity among all classes of visitors. The fact that it is open to the public on Saturday afternoons and Sundays until 4 p. m. has enabled many who would not otherwise find it possible to view the displays during the weekends.

The number of specimens and species on display has varied somewhat during the year, but, as a general rule, approximately 1,500 individual specimens, representing about 50 varieties, are shown in

the 47 tanks and 3 floor pools.

A consignment of spoonbill catfish (Polyodon spathula) collected from the Ohio River was received. However, the shipment arrived during the rainy season and the fish were unable to endure the chlorine in the water. Small activated carbon filters have been installed for the purpose of removing as much of the chlorine as possible in order to maintain the species that are susceptible to this chemical.

Further experiments were made with potassium permanganate in the treatment of fish affected by external parasites, expecially with regard to the application of such remedial measures to specimens held in outdoor pools.

The seasonal miniature hatchery, which is a special attraction to biology classes, was on display for the purpose of illustrating the meth-

ods utilized to incubate non-buoyant and semi-buoyant eggs.

In addition to holding fish in the reserve tanks for distribution to applicants in this locality, the aquarium was used in preparing and forwarding shipments of live fish and eggs to Puerto Rico and Colombia.

### DISTRIBUTION OPERATIONS

As the majority of distribution-car trips are made from stations in the Mississippi River territory, this service was partly decentralized during the year by the assignment of an Assistant Superintendent of Distribution to the La Crosse (Wis.) station. This procedure will expedite distribution, inasmuch as it is often necessary to move fish in that area without delay. This condition was brought about by the fact that the ponds constructed in the Mississippi River refuge have been very productive, and proper holding facilities for large numbers of fish are not available.

The same number of fish can be carried by truck as by distribution car, to destinations within a radius of approximately 300 miles, at about one-fourth the cost. For this reason the Bureau is purchasing additional automotive equipment, as funds permit, and car No. 7, the oldest distribution car in Bureau service, was decommissioned and

recommended for condemnation.

Many types of aerating equipment are in use at present by various Government and private agencies engaged in the distribution of fish by truck. The purpose of this equipment is the maintenance of the oxygen content and temperature of the water in the truck tanks at a level best suited to the fish during transportation. The Bureau's distribution trucks have been equipped with several different types of aerating apparatus in an effort to determine, from experience in actual use, which is best suited to this service. Upon conclusion of these trials the type of apparatus which has rendered the most satisfactory service

will be adopted as standard.

Truck deliveries during the year aggregated 333,950 miles, exclusive of the distance traveled by National Park, National Forest, and State conservation department trucks engaged in the distribution of fish produced at Federal hatcheries. Neither does the above figure include travel by individuals and sportsmen's organizations who called at the hatcheries to receive their allotments of fish. The distribution cars engaged in the delivery of fish to applicants, and transfers of fish between hatcheries, made 77 trips during the year and carried an average of 260 pails per trip. The cars traveled 52,899 paid miles and 11,789 free miles. Detached messengers traveled 45,152 paid miles and 1,639 free miles in delivering fish to applicants. The Bureau was again favored with free transportation and reduced rates by a number of the railroads.

### Summary, by States, of the distribution of fish, fiscal year 1939
