## THE NORMALS OF THE DAILY TEMPERATURE AND THE DAILY PRECIPITATION IN THE UNITED STATES.

The temperature data contained in the report on temperatures and vapor tensions of the United States, reduced to a homogenous system, gave the values for each month of the year and generally for the period 1873 to 1903. In the compiling of the climatological bulletins, which show a variation of the temperature and the precipitation for the current week, being published weekly, it is necessary to have normals which are available for any successive seven days which may occur in the year. For this purpose the monthly normals have been extended to normals available for each day of the year. In the case of the temperature this was accomplished by plotting down on a large sheet the monthly normals, drawing a curve through the twelve points representing the months, and then scaling off the temperature for each day. The monthly means were then taken from these values, and in case of any discrepancy between these monthly means and the original monthly normals the curve was slightly adjusted, so that these two monthly means should be in very close agreement. The tables of the daily normal temperatures for the several stations, giving the temperature each day to the nearest degree, were obtained in this manner.

In forming the daily normals of precipitation, the procedure was of a different character. For each station all the records of precipitation for each day in the year were collected together, using the entire available series during which observations were made at a given station. The daily means of these data were taken, and the result of plotting these values in a curve shows that the record is by no means long enough to give a true normal value, the curve being generally rough and consisting of broken lines. This is due chiefly to the fact that occasionally the effect of a storm is to produce excessive local precipitation on the given date, but as the occurrence of this storm is more or less accidental at a given place it will require many more years of observations to eliminate this irregularity than we now possess. In order to approximate closely to the daily normal values which would be derived from a very long series of observations of precipitation, covering two or three centuries, it was thought proper to use the mean values of successive eleven dates—that is, beginning with January 1 to 11, inclusive, the mean precipitation was taken and entered against January 6; then taking January 2 to 12, inclusive, the mean precipitation for these dates was entered against January 7; and in this way the normal values were obtained for each day in the year. This smoothing process evidently tends to spread the excessive values of individual dates backward and forward through ten dates on each side of their occurrence, and this well-known process gives a very close approximation to the mean curve which would result from a very much longer series of actual observations.

In the cases of stations of short record, as compared with many stations covering thirty-three years, the following process was adopted for adjusting short records of precipitation to the corresponding long records:

A series of charts were prepared for every tenth day, as January 1, January 11, January 21, February 1, etc., on which were entered the values of the precipitation for every tenth day, using all the stations of long record, which covered the map of the United States quite fully. Then the values for each tenth day of the station with short record were compared with those in its neighborhood, and such adjustments made as seemed to be justified. The daily normals were then interpolated between these 10-day values, in every case being guided by the trend of the corresponding daily normals of the neighboring stations of long records.

These tables of daily normal temperature and precipitation are now in use in the climatological work of the Bureau throughout the United States, and they have superseded all the daily normals which were prepared several years ago from much less extensive data than were available in the formation of these tables.

I have been assisted by Mr. H. L. Heiskell and Mr. C. Grant Bigham in the preparation of this report.

Annual, 46.14.

These normals were determined by subtracting 7 per cent from the means of the records by the city engineer. A comparison of four years' record shows that the gage at the Weather Bureau office catches about that amount less than the one at the city engineer's office, due probably to the difference in the elevation of the gages. The daily values were scaled by comparison with surrounding stations.
